On the 10th of March last, I was consulted by a medical student, aged 17, who was much annoyed by the very frequent occurrence of seminal emissions, to the extent of two nightly at times. I simply prescribed the following: R. Pulv. camphoræ gr. xvij; pulv. opii gr. xij; ext. hyoscyami q. s. ut fiat massa, et divide in pilulas xij. One pill was ordered to be taken at bedtime; and forty minims of tincture of steel to be taken thrice daily in a wineglassful of water. Ten days afterwards, the patient called upon me, delighted to find the source of much annoyance removed.

I was consulted by a patient at a very considerable distance, regarding the same affection. In a communication dated December 10th, 1867, after a truly amusing description of his symptoms, but one displaying almost "a mind diseased," the patient stated: "I have emissions almost every night, and sometimes twice a night. It is about two years since I suffered from them." I ordered my usual prescription. On the 28th March following, he writes: "I have had only one emission during the last thirty-three days." I advised that the dose of the tincture of sesquichloride of iron should be gradually increased to ninety drops. My patient was evidently so satisfied with its efficacy, that he exceeded my allowance. "I am at 120 drops now, thrice daily"; and he adds, "I am quite cheerful at present."

Dr. Bradbury remarks: "Wherever, therefore, there is reason to believe that nocturnal urinary and seminal incontinence are due to spasm (not the result of irritation reflected from a fissured anus, worms, urinary calculi, congenital phimosis, or of structural disease of the walls of the bladder, etc.), hydrate of chloral will be found a most serviceable drug in their treatment, in consequence of the acknowledged efficacy of this drug of allaying spasm, as observed in tetanus and other spasmodic disorders." My belief is that no abnormal spasm ever takes place without some primary irritation. Is there no irritation in tetanus? Is hysteria not traceable to uterine, ovarian, or vaginal hyperæsthesia? Does the removal of the testicles in cases of epilepsy in the insane, and the marked benefit attending the operation, not indicate the removal of a source of irritation? And wherein does Mr. Baker Brown's operation of clitoridectomy differ from this operation? Is erotomania not insanity? It is a wise advice that of two evils we should choose the lesser. And can the "culpability" of removing the clitoris with the consent of the sane, or without the consent of the insane, be urged against the bodily risks and appalling spectacle presented by an epilep-

tic, and the moral degradation of a debased practice, or the instrumental prostitution of these latter days? What of the cases of partial paralysis from reflex irritation, caused by congenital phimosis and adherent prepuce, as recently reported by Dr. Sayre, of New York?

While it is very possible, then, that hydrate of chloral may act beneficially in cases where irritation alone is to be contended against, I am very doubtful of its efficacy where muscular debility has been superinduced by chronic hyperæsthesia.

In a word, my experience of the use of the above drugs, is that they will cure urinary or spermatic incontinence (confining this term to the exceptional cases in which this condition absolutely exists as a pathological state) in the great majority of cases, always providing that the tincture of steel be given in the large doses mentioned, and sufficiently diluted. And contrary to what might be anticipated when the system becomes thoroughly saturated with the tincture, the bowels become rather loose than costive. As a narcotic in the cases under consideration, I cannot decide between hyoscyamus and belladonna. I sometimes use the one, sometimes the other. I have pushed belladonna to the extent of causing dryness in the throat and impaired vision, and I have never known it, as Dr. Bradbury has, to cause diarrhœa. These are subjects upon which very much might be said, and on which too much of a kind has been said. In the meantime, I content myself with confidently recommending an older treatment than that by chloral, and with expressing satisfaction at the appearance of Dr. Bradbury's paper.

## ABSTRACT OF CLINICAL LECTURE ON SUPPOSED CASES OF HYSTERIA.

*Delivered at St. George's Hospital on October 30th, 1871.*

By H. W. FULLER, M.D.,

Physician to the Hospital.

GENTLEMEN,—In the absence of any new form of disease in the hospital, I propose to speak to you of two interesting cases which were admitted as cases of hysteria. The one is in the Peppys Ward, and the other in the Holland Ward. The first instance is a remarkable one. The girl's physiognomy was that of hysteria, and she had attacks of a very violent character. In her fits there were the most terrible struggles; but throughout them she possessed consciousness, and she would try to bite any one attempting to hold her. She had no true convulsions, as in epilepsy, yet she had violent muscular jactitations, and appeared to have little control over her movements, so that she would injure herself severely by knocking her head against the wall or bedstead, unless she were prevented. She reported that she was a healthy girl till a week or ten days before her admission, when she received a blow on the head. From that time, she generally had great pain in the head. Two days after receiving the blow she had the first attack, and those who saw it regarded it as hysterical, and treated her accordingly. She was the picture of health, with clean tongue, normal pulse, etc. However, on inquiring into the case, I found that she did not sleep well, that she had a peculiar heavy look, and complained of increased pain in the head before the attacks. She was observed in her sleep to put her hand to her head. One day I saw her in an attack, one of the most violent I ever witnessed; and in it, although the muscular movements were so violent that four persons could scarcely hold her, she retained a considerable amount of consciousness. Her tongue was protruded, but was not bitten; she made frequent attempts to bite those who held her, and she did not go to sleep when the fit was over. In many respects, then, the attacks resembled attacks of hysteria; but, coming on as they did, irregularly, preceded by heaviness, restlessness, and severe pain in the head, I am inclined to regard them as denoting some mischief about the brain—a kind of hysterical epilepsy. In the first instance bromide of potassium was given, and for a month she took it in full doses of half a drachm four times daily, but no appreciable effect was produced. The fits recurred as often as ever—not infrequently two or three times a day; the same heaviness of aspect continued, and there was the same constant complaint of headache. I therefore put her upon the biniodide of mercury, and from that time she began to improve, and for the last week has not had another attack. Whether this will continue remains to be seen; but certain it is that she has greatly improved since she began this treatment. My impression is that in this case we have to deal with real mischief—not with mere hysteria—with local cerebral congestion and irritation occasioned by the blow, the hysteria being only superadded to it; and I would warn you that you may get into great mistakes and trouble in these cases if you do not note carefully *all* the symptoms before allowing yourselves to arrive at a conclusion. I remember a man in the King's Ward who was regarded

by everybody as hysterical or hypochondriacal, and was treated for that disease by assafoetida, etc.; but one day the man fell down in a fit and died. An abscess was found in his brain. He complained of one painful spot in his head day by day, and maintained that nothing removed it or influenced it. Where you find such a pain complained of continually, and without variation in its seat or character, you will do well to pay heed to it, and not to regard the patient as a hypochondriac. One young lady whom I knew complained always of a pain just at the junction of the spine with the neck. The pain was constant, and was invariably referred to the one spot, and all other suffering was disclaimed with an earnestness not common in hysteria. The constancy and severity of the pain made her nervous, and she was regarded as hysterical, and treated accordingly by the physician attending her. One day he was hardly out of the house when he was hurriedly sent for, but she had fallen down dead. A small aneurism was found, causing erosion of the spine, without giving rise to any of the ordinary symptoms.

Dr. Fuller then noticed a case of true hysteria in the hospital, and contrasted the symptoms presented with those of the girl first brought under notice. He then referred to cases of hypochondriasis connected with the excretion of excessive quantities of nitrate of urea, and pointed out how the symptoms in these cases differ from those met with in hysteria. He then proceeded to allude to the connection between hysteria and uterine irritation, and deprecated the course often pursued of employing specular examination in young girls who presented no symptoms of uterine mischief other than that of leucorrhœa. He believes that the great majority of such cases have a constitutional origin, and are to be remedied by treatment addressed to the improvement of the general health. In many such cases the bowels are habitually constive, and, as long as the secretions from the bowel are allowed to continue scanty and unhealthy, so long the remedies employed will usually fail; but as soon as a free daily action of the bowels has been induced, the source of irritation seems to be removed, and in most instances not only will the general health improve, but the uterine and hysterical symptoms will disappear.

## THE ANTISEPTIC TREATMENT OF SMALL-POX.

By ARTHUR ERNEST SANSOM, M.D. Lond.,

Physician to the Royal Hospital for Diseases of the Chest, and to the North-Eastern Hospital for Children.

THE interesting communication of Dr. Hjaltelin on "Small-Pox imported into Iceland by French Fishing Vessels, stamped out by Quinine and Sulphurous Fumigations" (BRITISH MEDICAL JOURNAL, November 4th, 1871, p. 519), affords most valuable evidence in support of the opinion I have often submitted—that the course of zymotic diseases can be modified in intensity and in duration by the internal administration of antiseptic agents. The following case, though, of course, individual instances can have but little value as evidence in regard to the major proposition, may serve to illustrate the method of putting in force the antiseptic treatment of the disease.

I was called on October 13th, 1871, to visit Miss E. T., aged 18. She had high fever, delirium, and vertigo. The pulse was 128. Temperature, 105 deg. Fahr. The tongue was red, dry, with brown streak down the centre; the pupils were widely dilated. A few spots closely resembling those characteristic of typhoid existed on the abdomen, but there was no abdominal tenderness, distension, nor diarrhœa. The diagnosis was complicated, for the young lady had lately been staying in a locality wherein typhoid was prevalent. There was no lumbar pain. I gave a guarded diagnosis, but considered it most probable that the case would prove to be one of typhoid. I ordered cool sponging; milk and beef-tea; half an ounce of brandy every four hours; a scruple of sulphite of sodium in solution every four hours. On October 14th, the pulse was 124; the temperature was reduced to 102 deg. Fahr. Several papule were present upon the face. The case now assumed the aspect of variola. On October 15th, papule were abundant over the face, arms, and legs. On October 16th, all signs of general discomfort had subsided; the patient only complained of irritation of the papules, which began to become pustular. On the 17th, I touched the centre of each pustule on the face (over sixty in number) with a fine camel's-hair pencil, dipped in strong liquid carbolic acid, taking care not to allow any to reach the sound skin, and ordered a solution of one part of carbolic acid in three of olive oil to be applied over the individual pustules night and morning. On October 18th, the patient slept well, all irritation from the pustules having subsided. The carbolic liniment was continued; the surface of the skin was sponged now and then with oatmeal water. The temperature from this date never rose above the

normal; there was no discomfort whatever; the pustules all dried up, and, on the eighth day, a large number had completely fallen off, leaving no cicatrices; the others were quite dry and scaly. On October 23rd, the sulphite of sodium was discontinued, and sulphocarbonate of iron given in five-grain doses three times a day. The surface of the body was washed with coal-tar soap to aid disinfection.

The double principle of the antiseptic method of treatment is the arrest of the disease-process in the individual, and the prevention of spread to the community. The same class of agents which common experience declares to be disinfectants, can be administered to the living body with at least a fair hope of their accomplishing that destruction of disease-germs which they accomplish externally to it. Carbolic acid has been administered by many, especially by French, physicians. But I believe that, in many cases, carbolic acid and its compounds can be advantageously replaced by other antiseptics—especially in those wherein head-symptoms are prominent. I think it very probable that we shall find certain antiseptics are best suited to the treatment of certain diseases; in scarlatina, diphtheria, and all zymotic ailments in which the throat is involved, I have found the sulphocarbonates specially valuable. In his successful cases of variola, Dr. Hjaltelin employed the ordinary sulphurous acid in fluid-drachm doses every third hour. I have rather inclined to the use of the sulphites recommended by Polli—they are powerful and direct antiseptics, easily administered and readily absorbed. I believe that in this country the error has been made of administering them in insufficient doses, or else of employing the hyposulphites—purgative salts, and far less efficient as antiseptics.

The external treatment of the pustules is most important. No agent seems to me so valuable as carbolic acid; its application in the pure form to the summit of each pustule is perfectly painless. It is not necessary to touch each individually at one visit, but at subsequent times to touch those which have been omitted previously. I have found nothing so effectually disguise the odour of carbolic acid, without impairing its antiseptic efficacy, as oil of wild thyme (*oleum origani*). Thymic acid is itself a well-known antiseptic. The effect of the application of the carbolic acid is at once apparent; the pustule first becomes white, and then dries up. The carbolic oil afterwards applied, penetrates amongst the purulent crusts, and is far more efficient than any watery application. The general surface of the body may likewise be sponged with any soluble antiseptic. I believe the coal-tar soap to be very valuable for washing the surface of the body. By the antiseptic method of treatment, external as well as internal, the patient is really disinfected from the onset of his malady, and the benefits are manifest alike upon himself and upon those subject to the contagion.

## OBSTETRIC MEMORANDA.

### FLEXIONS OF THE UTERUS.

THE case of retroflexion of the uterus described by Dr. Boulton in the number for November 4th, raises in my mind the doubt whether it is necessary or advisable to shore up the simply retroflexed uterus (especially if in a virgin) by the contrivances therein described. As a general practitioner, such cases frequently come under my care, and are generally complicated with some inflammatory or ulcerative mischief in the os or cervix. I have always treated first the inflammatory or other affection; and generally find, when that is cured, that no inconvenience arises from the retroflexion. Should any pain or discomfort continue, I find a simple Hodge's pessary answer every purpose, without danger or inconvenience to the patient.

J. WALTERS, M.B., Reigate.

### LABOUR OCCURRING WITH AN UNBROKEN HYMEN.\*

ON Tuesday, October 17th, 1871, at 1.30 A.M., I was called to attend Mrs. F. of Lancaster in her first confinement. She was in her twentieth year, had always enjoyed good health, and menstruated regularly previous to her marriage. On making the usual examination, I found the vagina closed by a firm membrane, through which I could detect no opening, nor could I feel any pressure against it during the pains. On examination by the rectum, the head could be obscurely felt at the brim of the pelvis. She had strong pains till 4 A.M., when she fell asleep, and I left her. At 9 A.M., I visited her again, and found she had had slight pains. After a very cautious examination with the finger, I found a small slit, like the orifice of the female urethra, and with some difficulty introduced a finger and felt inside the os uteri slightly dilated and the head presenting. At half-past 10, I met Mr. Howitt in the

\* Read before the Liverpool Medical Institution.

neighbourhood and took him with me to the case. He passed first one and then two fingers, and satisfied himself that the os uteri was within and behind. No pains occurring, I left her till 1 P.M., when strong labour set in. At 2 P.M., the liquor amnii came away; the os uteri could then be distinctly felt, about half dilated, and about half an inch higher than the orifice. Labour progressed steadily. At 4, a portion of caput succedaneum made its way through the opening; and at half-past 5, the whole child passed, and delivery took place. After delivery, a circular band remained round the vagina. The patient did well; the child was a well-developed boy. I gave her no medicine, and in no way interfered with the natural course of the labour.

C. JOHNSON, F.R.C.S.E., Lancaster.

#### RUPTURE OF MEMBRANES SIX WEEKS BEFORE DELIVERY.

ON October 2nd, 1871, I was sent for to attend Mrs. S. in her confinement. On my arrival, I found the membranes ruptured, the os uteri of the size of a shilling, and the head presenting. The pains occurred at intervals of about ten minutes, and were accompanied each time by a free discharge of liquor amnii. Mrs. S. was the mother of ten children, and all her previous confinements had been perfectly natural. She was of opinion that she had gone her full time, and believed that labour had commenced. No progress being made during the hour or so that I stopped, I told them to send for me when the pains became more severe. As I received no message during the day, I called in the evening, and found my patient free from pain and all signs of labour; the abdomen was notably smaller, and she expressed herself as easier than she had been for a month. Matters continued much in the same state for the next six weeks; she gradually increased in size; and when the abdomen attained a certain dimension, periodic pains ensued, accompanied by a copious discharge of liquid, which always gave great relief. Besides these occasional floodings of water, there was a constant drain going on, so that she found it impossible to keep herself dry. At length, on November 15th, 1871, labour-pains really commenced, and in less than an hour she was delivered of a fine male child, just six weeks after the rupture of the membranes.

S. MESSENGER BRADLEY, F.R.C.S., Manchester.

### THERAPEUTIC MEMORANDA.

#### THERAPEUTICAL RELATIONS OF ASTHMA AND GASTRALGIA.

THE perusal of the paper in the JOURNAL of November 11th, on the relations of asthma, angina pectoris, and gastralgia, leads me to send some short observations which I find in my hospital note-book of the date April 28th, 1870. Mrs. W., a patient who had had pure typical gastralgia, was at that date amending, partly under the influence of one-drop doses of Fowler's solution, and she has been discharged cured. At the very same date, Miss W., daughter of the above, was under my care for asthma, against which I had placed in my notes "pulmonary neurosis". She was speedily and effectually relieved by two-drop doses of Fowler's solution in infusion of calumba. About the same time a man was for a long time under my care for flatulent dyspepsia and most intense neuralgia of the fifth nerve. I cannot say arsenic did him any good, though bismuth seemed of some service for a time. Premature greyness of the hair seems to me common in some of these cases of dyspepsia of gastralgic type.

JOHN C. THOROWGOOD, M.D.

November 15th, 1871.

#### REVACCINATION BY VESICATION.

IN several letters which have appeared in the JOURNAL respecting the method of introducing the vaccine lymph into the system, which I have brought before the profession, it is recommended to use the liquid vesicator for producing the blister. I have for a long time past discarded this as uncertain, and I recommend all who wish to try this method of vaccination to do so in the following manner. Take a piece of soft adhesive plaster—that spread on "mole-skin" is best—about an inch and a half long by three-fourths of an inch broad; upon this place two or three small bits of emplastum lytta (the old-fashioned and excellent blistering plaster), pressing them firmly, so as to make them adhere to the plaster beneath. These pieces of blister ointment must not exceed the size of a split pea, and may even be less with advantage. The plaster thus charged with the vesicating spots is to be firmly pressed

down upon the arm in the usual position and made to adhere. This is done the night before, and next morning the tiny blebs are opened, the serum let out, and the vaccine-charged ivory point introduced, one into each spot. When carefully done, success is absolutely certain.

ROBERT ELLIS, Sloane Street.

#### COLO-PUNCTURE IN TYMPANITES.

THE numerous and valuable communications elicited by the publication of my paper on "Colo-Puncture", in the JOURNAL of October 21st, prove that this operation had been both recommended and practised at an earlier period than either other writers on the subject or myself were aware. I think, however, that the operation had become neglected and not appreciated as a legitimate surgical procedure until some four years ago, when it was revived by several independent thinkers. It is evident from Mr. McBride's communication, that colo-puncture in the human subject is not (as was supposed) an analogous operation to that performed on cattle. We have now, however, so considerable an experience of the operation of colo-puncture, that we may fairly claim to form an opinion on its merits. There are four cases reported in the *Practitioner* for this month by Dr. Clifford Allbutt, which must be added to those already quoted. Dr. Fonssagrives, in his paper before the Academy of Medicine, cites eighty-four cases, in which, in all probability, are included some of the cases recorded in this country. The evidence appears to be unanimous in favour of the great relief which can be afforded by puncture in these distressing cases of tympany, and that the possible risks of the operation are not borne out by *post mortem* examination.

Let us for a moment inquire what are the risks attendant on puncture of the intestine. They appear, to my mind, to be two—viz., extravasation of feculent matter into the peritoneal cavity, and the infliction of a lesion on the peritoneum, already perhaps in an acute inflammatory state. The size and character of the puncture, when made with a fine trocar and cannula, are such, I think, as to bring the chances of extravasation very low. The puncture merely separates the muscular fibres, and, on the withdrawal of the cannula, the muscular planes immediately readjust themselves, or a protrusion of mucous membrane takes place, which entirely prevents the escape of the intestinal contents, as was demonstrated by Travers in cases of punctured wounds of intestine where the incision did not extend beyond three lines in length.

The influence of pressure of the abdominal walls and contents in cases of non-protruding wounded intestine is clearly shown by Mr. Erichsen (*Science and Art of Surgery*, p. 403, fourth edit.), where he states that feces escape from a smaller aperture in a protruding than in a non-protruding intestine. He also refers to two cases of wounds of intestine without any extravasation. A similar case occurred in my father's practice, where a man while killing a pig stabbed himself accidentally in the abdomen; the intestine did not protrude, but the patient passed a large quantity of blood *per rectum*. He recovered without a single symptom of extravasation. Clinical experience, therefore, shows that punctured wounds of the intestine (non-protruding) of less than three lines in diameter, may be said not to allow fecal extravasation. The lesion in colo-puncture comes so much within these limits, that I venture to think it may not deter us from resorting to this method of, at the least, relief. As has been ably shown by Dr. Braxton Hicks, the tympanites which often accompanies peritonitis adds so much to the distress and danger of the patient, that I quite agree with him in the propriety of puncture, even when the peritoneum is acutely inflamed. The well-known case of ovariectomy during an acute attack of peritonitis, by my friend, Dr. Alfred Wiltshire, demonstrated the justifiability of producing a most severe lesion of the peritoneum when our object is to relieve a state that at any rate aggravates matters.

J. HANCOCKE WATHEEN, L.R.C.P. Edin., M.R.C.S. Eng., etc.  
Fishguard, November 14th, 1871.

MUSCLE-GRAFTING.—Dr. Benjamin Howard, referring to the generally expressed belief, formularised by Mr. Steele in his clinical lecture in the BRITISH MEDICAL JOURNAL (December 10, 1870), that "It is evident that all that is essential is the papillary layer of cutis, no matter how small, capable of developing cuticle," relates two cases in which he employed small muscle grafts. They had precisely the same beneficial effects in these cases, of which details are given (*New York Medical Journal*, Sept. 1871, p. 279), as we are now accustomed to observe in successful cases of skin-grafting. Dr. Howard concludes "That neither the increased vascularity of the surface of the wound, nor the centripetal cicatrization induced by the skin-graft, is in any way due to the epithelium in the graft." He does not, however, of course propose muscle-grafting as a substitute for skin-grafting.

## REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN  
THE HOSPITALS OF GREAT BRITAIN.

## UNIVERSITY COLLEGE HOSPITAL.

## CASES OF LITHOTRITY.

(Under the care of SIR HENRY THOMPSON.)

ON operation day at this hospital, two cases of stone which presented some features of interest were operated upon by Sir Henry Thompson. In the first case, the patient, a man about sixty years of age, had been sounded in the usual way some days previously, and a small stone discovered. The sound used was a No. 8. On Wednesday the patient was put on the table and the lithotrite, of the size of a No. 13 or No. 14 catheter, was introduced, but would not pass into the bladder after various attempts had been made. A little blood flowed from the urethra. Under these circumstances, Sir Henry Thompson remarked that it was undesirable to proceed. He would leave the patient alone for a week, until the excoriation of the urethra had subsided, before he again introduced any instrument. It was occasionally found that the lithotrite could not be introduced without difficulty; but, in his experience, such cases were of the rarest occurrence. There could, however, be no ultimate difficulty, after preparing the urethra by dilatation, in introducing the lithotrite and crushing the stone.

A second patient, suffering from calculus in the bladder, was operated upon the same day. The patient was also about 60 years of age. The stone was of such a size that Sir Henry Thompson had at first remained uncertain whether it was suitable for crushing; but, as the stone was just on the borders of a lithotrite case, he had decided on crushing it. The instrument was accordingly introduced and the stone was crushed. One of the fragments was then seized and also crushed. The *débris* brought away between the teeth of the instrument showed the stone to consist of lithic acid and phosphates. No chloroform was used in either case, the pain produced by the operation being thus expressed by the second patient: "You have," he said to Sir Henry Thompson, "punished me less than the stone."

Several other cases were operated upon. In one, exploration of a diseased ilium was performed by Sir Henry Thompson, the clinical interest of this case resting on the fact that, as the patient's urine contained a large quantity of albumen from chronic kidney-disease and his legs were cedematous, it was thought inexpedient to interfere to any extent. No diseased bone was discovered after the sinuses had been enlarged. Under the circumstances, further interference was considered undesirable.

Mr. Berkeley Hill removed from a young child a testicle affected by encephaloid cancer.

## CHARING CROSS HOSPITAL.

## DISTURBED ACTION OF THE HEART.

(Under the care of Dr. GREEN.)

IN the out-patient department of this hospital, we lately observed a case of some interest under the care of Dr. Green. It was that of a man aged 47, who during the last three years had suffered from time to time from violent palpitation of the heart and dyspnoea. The patient was a labourer, and had led a somewhat irregular life. The palpitation was, more or less, continuous, and was much aggravated on taking the least exertion. The patient's general health was exceedingly good; he had no dyspeptic symptoms, and the palpitation was not increased after food. The heart's action was exceedingly irregular, both in force and rhythm. The impulse was distinctly heaving, and extended over a somewhat larger area than normal. The centre of the area of impulse was a little below and a little inside the left nipple. During a prolonged auscultatory examination, a systolic murmur was occasionally audible at the apex.

Dr. Green regarded the case as one of disturbed cardiac innervation, quite independent of reflex stimulation. The hypertrophy was the result of the increased action, and, as the centre of the area of apex-impulse was unaltered, it probably affected both the left and the right ventricles. The intermittent mitral murmur was probably due to the irregular contraction of the papillary muscles. The patient was almost immediately relieved by fifteen-minim doses of tincture of digitalis; whilst taking this remedy, he was able to continue his employment, and the symptoms did not recur.

## MIDDLESEX HOSPITAL.

## A CASE OF FATAL ANÆMIA.

(Under the care of Dr. GREENHOW.)

THE following report, with remarks, is by Dr. King, the medical registrar of the hospital.

S. D., aged 27, housewife, was admitted on September 7th, 1871. There was no history of gout, rheumatism, phthisis, nervous disorder, or other hereditary tendency in her family. The patient had the usual diseases of childhood, and was always rather delicate, and subject to palpitation. The catamenia appeared at fourteen, and since then she had had more or less menorrhagia and leucorrhœa. She never, however, had any serious illness till about a year ago, when she began to suffer from diarrhoea and vomiting, with occasional vertigo, but did not complain of pain after food, nor did she vomit blood or pass any *per rectum*. The palpitation now became worse, and was accompanied with pain between the shoulders. These symptoms continued for two or three months without any appearance of jaundice. She then got better, but three months afterwards was attacked in the same manner, with the addition of a slight yellow tinge of the skin and conjunctiva, and was again laid up for two months. After this, a second remission occurred, and she remained comparatively well till two months before admission, when the old symptoms returned as before. The patient was married five years ago, but had no family. She said that she had lost flesh a good deal during the last twelve months.

On admission, she was pale and delicate looking, but not emaciated; she complained of pain between the shoulders, palpitation, great weakness, vertigo, and depression. The pulse was 128, exceedingly weak, small, and compressible; respiration shallow, no cough or expectoration; temperature 100.4. There was no discoloration of the skin, which was almost as white as wax. There was, however, a faint jaundiced tint of the conjunctiva. The lips were wholly devoid of colour, and the tongue, though clean and moist, was pale, rough, and small. The extremities were deficient in heat, and shivered if exposed to the air. There was a loud double murmur over the precordial region, having a friction-like character, and a maximum intensity at a point just inside and a little above the left nipple. There appeared to be no enlargement of the liver or spleen; and beyond some slight tenderness at the epigastrium, probably due to frequent retching, there was no evidence of other abdominal mischief. The urine was acid, of specific gravity 1013, free from albumen or bile-pigment.

The further progress of the case was marked by increasing debility, constant nausea, and occasional vomiting. On September 20th there was some diarrhoea, but neither at this nor at any other time was blood observed in the motions. The pulse, respiration, and temperature remained much the same throughout, the latter never exceeding 102, and only on one occasion descending as low as 98.8. On October 3rd she vomited during the afternoon, and frequently during the night. The sickness continued, and she sank exhausted on Oct. 5th, at 8.50 A.M.

*Necropsy* twenty-six hours after death.—Rigidity was moderate. The body was not emaciated, but exceedingly anæmic. The arachnoid membrane lining the dura mater was spotted with minute ecchymoses, and a small quantity of slightly turbid fluid coated the surface of a portion of the hemispheres and dipped in between the convolutions. The brain itself was completely bloodless, but otherwise apparently healthy. There were a few old adhesions between the left lung and thoracic parietes, where also there was a small quantity of imperfectly formed lymph, the result of recent pleurisy. Both lungs were healthy, but minute ecchymoses, like those on the arachnoid, were observed on the pulmonary pleuræ. The pericardium contained about three ounces of clear fluid. Both heart and membrane were perfectly smooth, and free from any appearance of recent inflammation. Not more than about an ounce of thin pale and watery blood could be obtained from the heart and large vessels; and that was perfectly fluid, refusing to coagulate. On microscopic examination, the white corpuscles were not found to be in excess. The liver, spleen, kidneys, suprarenal capsules, lymphatic glands, pancreas, stomach, intestines, and uterus, were minutely examined; but, though all were intensely anæmic, no trace of organic disease could be detected in any of them.

REMARKS.—The abnormally high temperature during life, associated as it was with a nearly exsanguine condition of the body, and the complete absence of any organic mischief which would account for the symptoms and fatal termination, seem to point almost conclusively to a nervous origin of the disease. Blood ceased to be formed in sufficient quantity to maintain life. Yet the most attentive examination of the spleen, suprarenal bodies, lymphatic glands and other organs, failed to reveal any more serious morbid condition than that of simple anæmia.

Nevertheless, we cannot suppose that arrest of function ever occurs independently of morphological change; if, therefore, the organ by which such function is normally performed, present no trace of anatomical lesion, we must look to the nerve- or blood-supply on which the working of that organ depends. The submaxillary gland, for example, though structurally healthy and plentifully supplied with blood, will fail to secrete saliva if its ganglionic influence be removed by division of the chorda tympani, through which channel its cellular elements derive that attractive and selective force, which enables them to abstract from the blood the particular kind of material required for the formation of salivary fluid. As with secretion, so it is with nutrition; for, in all the more highly differentiated animals, it is through the medium of a nervous system that trophic force is furnished to preside over the growth and maintenance of tissue. Nor can we deny for the fluids of the body that which we admit to be true of the cellular instruments by which those fluids are elaborated. I think, therefore, that we may fairly assume that, just as arrest may take place in the formation of saliva through the suspended influence of a known centre, so also may arrest take place in the formation of blood by morphological changes occurring in nerve-cells, with which we are unacquainted.

On such a view, the case which has called forth these remarks must be regarded as one of defective blood-nutrition, or neurotic atrophæmia as it might be called, due to morbid changes occurring in nerve-centres connected with the sympathetic system, centres which normally preside over the blood-vascular and lymphatic glands, superintending the production of that highly complex fluid which it is the special function of those glands to elaborate.

Further, I think we can scarcely fail to be struck with the close resemblance between the symptoms observed in the above case during life, and those commonly ascribed to suprarenal disease, from which affection it seems indeed to differ, merely in the absence of pigmentation and capsular lesion. What little we know of the causes which give rise to pigmentary deposit, points to nervous origin; while the fact that both suprarenal capsules may be reduced to masses of cheesy material without leading to cutaneous discoloration, rather tends to show that these two morbid conditions may be the effects of a common neurotic cause, incomplete hæmatinic metamorphosis giving rise to pigmentation of the skin, and suspension of trophic influence resulting in capsular disease. Be this as it may, we are bound to admit that there are other constituents of the blood quite as important as its pigment, which, though not dependent on the capsular bodies, are none the less indebted to trophic nervous influence for their proper elaboration; and if this be true, I see no reason why nerve-lesions should not exist, analogous to those which appear to be the cause of Addison's disease, giving rise to nearly the same train of symptoms, the same cachectic condition, and the same fatal termination, without necessarily leading to the development of those characteristic features by which the neurosis is commonly recognised.

### BRISTOL ROYAL INFIRMARY.

#### AMPUTATION OF THE FOREARM IN AN OLD MAN.

Under the care of Mr. C. STEELE.

GEORGE ALDEN, aged 74, a short, thick-set old man, was admitted on May 10th, for extensive disease of the left carpus. The history which he gave was that three years previously he sprained the wrist; that it became inflamed, was lanced, and disease of the bones followed. Sinuses formed a year and a half after the accident, and had since continued to give vent to discharge. He had been unable to work for a year and a half. He carried the hand in a sling, resting on a splint, and felt little pain except when any movement took place; he felt weakened by the discharge. The hand and wrist were much swollen; a considerable amount of fetid pus escaped during the day. When the hand was taken hold of on each side and moved, the bones grated on each other like stones in a bag, showing that they were all necrosed, denuded, and loose. A probe inserted proved the metacarpal bones to be necrosed. Mr. Steele explained to the patient that the only surgical treatment which could be adopted was amputation, but that he and his colleagues left it to his own decision, as the disease would probably remain in its present condition during his remaining years; whilst, however, if the limb were removed, and he survived the operation, he would, besides losing all discomfort, become much stronger. The patient returned home to Wales to consult his friends; by some he was strongly urged to retain his hand; by others to undergo the operation. He at last determined to have the question settled by losing the member; and accordingly returned on July 7th to be operated upon.

On July 9th, Mr. Steele amputated by Teale's operation at the middle third of the forearm. A number of rigid-walled vessels had to

be ligatured. The shock was very slight. Most of the extremity of the flaps united by first intention; pus was formed in the interior on the second day, and escaped at the lower border, where a plug had been inserted at the time of operation. The patient felt very well, and wanted to get up on the third day, and hoped he would be allowed to go home in a fortnight. On the eighth day after operation, the discharge became offensive; chloralum lotion relieved but did not destroy the fætor; sulphocarbolic lotion was tried, but with no better effect. The ligatures separated from the fifth to the eighth day. A gland in the axilla inflamed and suppurated, forming an abscess, which required to be opened on the eighteenth day after operation; linseed-meal poultice was applied for five days, and then simple ointment. The stump was dressed with simple ointment for some time; afterwards the granulating surface becoming rather languid, sulphate of zinc lotion was used. His appetite was good from the first; he generally slept well, was soon out of bed, and, before long, able to go into the garden. He left the Infirmary on August 25th, with the stump nearly healed, and feeling much relieved.

He came on October 20th to inquire about an artificial hand. The wounds were all healed. He had a very good stump, and felt well and much stronger. He was advised to wait some time longer before having any appliance made, until the stump had lost all swelling and tenderness, and had become settled in size.

## REVIEWS AND NOTICES.

A SYSTEM OF MEDICINE. Edited by J. RUSSELL REYNOLDS, M.D., F.R.S. Vol. III, containing Local Diseases (continued). London and New York: Macmillan and Co. 1871.

THREE years have elapsed since we welcomed the publication of the second volume of Dr. REYNOLDS'S *System of Medicine*—a sufficient interval for the preparation and editorial supervision of the articles which are to complete the work. The editor informs us, however, that he "did not receive, many months after he expected to do so, the MSS. of those articles which were necessary to complete the section on Diseases of the Circulatory System, several of the papers on which subjects had been for a long time printed. A short time ago, therefore, in order to avoid further postponement, he decided to change the order of sequence originally intended, and to publish first the section on Diseases of the Respiratory System." The present volume contains those articles which complete the section on Diseases of the Digestive System, and those which contain an account of Diseases of the Respiratory System. The fourth and last volume is expected to contain Diseases of the Circulatory System, of the Blood-glandular, of the Urinary, the Reproductive, and Cutaneous Systems.

This present volume is the more welcome, that we have been kept waiting for it; and, with the advantage of so many able pens and so accomplished a physician as its editor, it cannot fail to have many merits and to be well received. Sooth to say, however, its protracted gestation seems to have injured its development. It possesses all the faults of its race in an exaggerated form; and we do not remember ever to have seen a book containing so much good material, which is yet so seriously injured by bad arrangement, careless repetitions, irregular proportions, internal discordance, and generally by all the defects which editing is intended to avert or to minimise. Dr. Reynolds must allow us to say, with great regret, that, in respect to this volume, his authors, his publishers, whose enterprise and taste have laid the profession under a heavy debt, and the medical public, who must perforce buy a volume which is one of a series, have almost equal reason to complain of him. This volume is in truth no part of a system. It is a bundle of ill-matched, ill-assorted, and ill-proportioned essays, including many of a high degree of individual excellence.

The first article in the present volume treats of diseases of the Mouth, Fauces, Pharynx, and Oesophagus. It is not easy to understand why this did not precede the article on Diseases of the Stomach in the former volume. Dr. Squarey's article on the subject bears evidence of having been written by a physician who is well versed in the literature of the subject, but bears very little trace of practical familiarity with its theme. The remarks which he makes on lancing the gums are judicious, but not novel. Its author has borrowed very liberally throughout from Dr. West's book on the *Diseases of Infancy and Childhood*.

The essay on Enteralgia is by Dr. Wardell of Tunbridge Wells, and reflects no small credit on that provincial physician. It is work-

manlike and thorough, as are the rest of the essays which he contributes to the present volume. Dr. Bristowe, of St. Thomas's Hospital, furnishes the articles on Enteritis, Obstruction of the Bowels, Ulceration of the Bowels, Cancerous and other Growths of the Intestines, Diseases of the Cæcum and Appendix Vermiformis; and, as might be expected from his well known reputation, treats of all these subjects in a masterly manner. The first disease in this category is treated as a simple inflammatory affection, and divided according to an anatomical arrangement. The author says; "The intestinal tissues are all of them liable to inflammation, either separately or in combination; and the inflammatory process, as it occurs in each, has a tendency to present characteristic peculiarities, and to be associated with special symptoms." (P. 56.) Inflammation, as affecting the mucous membrane of the bowels, is again subdivided into (a) catarrhal, (b) croupous, (c) chronic inflammation and degeneration. Dr. Bristowe is of opinion that young children, especially during the period of dentition, are specially liable to catarrhal inflammation of the intestines. He also quotes Dr. Fenwick's opinion as to the affection being generally attendant on scarlatina and other specific fevers. We quite agree with the statement that "croupous" (diphtheritic or membranous) inflammation of the intestines is far from uncommon. We had lately under our care a case in which shreds of false membrane were passed by the bowel, and in which there was no diarrhoea or hæmorrhage from the bowel, but, on the contrary, constipation. Dr. Bristowe's remarks on the treatment of the more severe forms of enteritis (as affecting the whole thickness of the bowel) seem to us especially valuable. He says that these cases should be treated according to two main principles, which are, "first, to relieve pain, and prevent, so far as may be, all movements of the bowels, by means of opium; secondly, to avoid every attempt (at least until all grave symptoms have ceased) to force the bowels by the administration of purgatives. . . . No absolute rule can be laid down with regard to the quantity of opium which should be given for a dose, or to the frequency with which the dose should be repeated. The patient should, however, be got well under the influence of the drug, and should be kept under its influence." If the stomach reject the opium, he recommends that it should be administered in the form of suppository or enema, or injected subcutaneously. In his article on Obstruction of the Bowels, the author acknowledges his obligations to the excellent work of Dr. Brinton on *Intestinal Obstruction*, and to Dr. Fagge's excellent paper on the same subject in the *Guy's Hospital Reports* for 1869. In all cases of sudden obstruction, especially when attended with enteritis, the author says that purgatives must be discontinued, and opiates and other sedatives given in doses sufficient to alleviate pain and to ensure rest. He recommends their administration by subcutaneous injection. With regard to operations for the relief of obstruction, he says that they "are rarely followed by satisfactory results; nevertheless, if there seem a chance, however remote, of lengthening the life of a patient who is otherwise doomed to speedy death, few would hesitate to catch at that chance." (P. 103.)

Passing on to the articles on Colic, Colitis, and Dysentery, we are compelled to find fault with the editor. All these articles are really superfluous, the first subject having already been treated of under the head of Enteralgia, the second under Enteritis, and Dysentery having been discussed in the first volume by Dr. Maclean. Why should non-epidemic dysentery be separated from the epidemic form, and treated of separately?

Certain diseases of the Rectum and Anus are ably described by Mr. Curling. Although strictly belonging to a work on surgery, these articles will be found very useful to the physician.

Dr. Ransom of Nottingham contributes the article on Intestinal Worms, which, for completeness, leaves little to be desired. The descriptions of the more important entozoa which infest man are illustrated by drawings from Leuckart and Davaine. Viewing the articles on Diseases of the Intestines and of the Peritoneum as a whole, the defect of editing, which allows the same subject to be repeatedly treated of in more than one place, is very striking. Thus not only are the articles on Colic and Colitis, as we have just pointed out, altogether unnecessary, in consequence of these subjects having been fully discussed under the general heads of Enteralgia and Enteritis, but Villous Growths in the Rectum are described both by Dr. Bristowe and Mr. Curling; Perityphlitis by Dr. Bristowe and Dr. Wardell; also Enteritis in Children by the same writers; and other instances of the same repetition might be cited, did space permit. In the second part of the volume, as we shall see, some of the essays read as though expressly written with the view of refuting others in the same volume.

The first paper on Diseases of the Liver is an ingenious discussion by Dr. Anstie, on "Hepatalgia", which is defined as "an affection characterised by attacks of deeply seated pain in the region of the liver; intermittent, in the manner of neuralgias; attended

by no organic changes or febrile disturbance; not necessarily involving an interference with secretion; but occasionally attended with arrest or perversion of the biliary secretion, and consequent jaundice and stomach-derangement." The author speaks highly of the value of muriate of ammonia in this affection. Dr. Maclean contributes carefully prepared and interesting articles on Congestion of the Liver, Suppurative Inflammation of the Liver, and Gangrenous Inflammation of the Liver; whilst Dr. Goodeve gives good accounts of what is known on Jaundice, Biliary Calculi, Cirrhosis of the Liver, and Acute Yellow Atrophy of the Liver. The last named author quotes extensively from the classical works of Frerichs, Budd, Harley, and Murchison, but affords us reason to regret that he has not drawn more extensively on the results of his own Anglo-Indian experience.

The remaining articles on Diseases of the Liver—viz., Fatty Liver, Cancer of the Liver, Hydatid Disease of the Liver, and Waxy Disease of the Liver—are by Dr. J. Warburton Begbie of Edinburgh. This accomplished clinician, curiously enough, modestly leans chiefly upon the works of his predecessors; and the essay is more remarkable for its apt and full references than for that peculiarly clear and thoughtful summary of bedside experience which often distinguishes his works.

[To be continued.]

## REPORTS AND ANALYSES

IN

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### MEDICINE-CHEST.

WE have had brought under our notice a very convenient and inexpensive medicine-chest, manufactured by Messrs. Green, Wenman Street, Birmingham. The contents appear to be of good quality and well selected, and include everything which is necessary for family use or for the medical practitioner in an emergency. We think that it satisfies a want, and will be much valued by parents of families. It will be of no small service to medical practitioners whose patients reside at a distance.

#### PHARMACEUTICAL PRODUCTS.

AMONG the most interesting and important exhibits in the pharmaceutical department of the Annual Museum of the Association at its Meeting in Plymouth were those of Messrs. Southall, Son, and Dymond, of Birmingham, which we noticed briefly in our review at the time. They comprised, *inter alia*, a series of specimens of opium, which, though they appeared to the naked eye of about equal merit, had yet been proved by analysis to vary, as regarded the morphia they contained, from 2 per cent. to 10.5 per cent. This very striking difference shows how important it is that, in making such preparations as tincture of opium, the opium should not be estimated by its market price, this too often being fixed by its naked-eye appearance, not by its actual alkaloidal value, which can be ascertained only by analysis. It also explains very readily how it is that laudanum may differ so much as it is practically found to do in energy.

Not less interesting and important was a new preparation of the cinchona alkaloids. The able Report of the Indian Cinchona Commission shows that the various alkaloids derived from the cinchona barks have about an equal therapeutical value. Sir R. Christison is of opinion that, of all galenical preparations of cinchona, the simple powder is the most trustworthy. Its nauseousness and bulk drove it out of practice, and the elegance of the present age will most certainly keep it out. Messrs. Southall have skilfully managed to restore to us the use of the powder without its nauseousness. In quinine, as they term it, we have, in the shape of a brownish powder of not very bitter taste, all the active elements of cinchona without its woody fibre. This is capable of being made up in several elegant and agreeable forms. It may be given in pills, or in the shape of liquor quinine. The Museum contained specimens of quinine combined with chocolate in the shape of pastilles, which are most agreeable to the taste for children or fastidious persons. We have recently examined these preparations carefully, and can speak very highly of them. The quinine pastilles are admirably convenient.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 25TH, 1871.

### THE COMING RACE.

MR. BERKELEY HILL addresses to us a communication which may be commended to the attention of students, of metropolitan and provincial examiners, and of the examining body and councillors of the College of Surgeons. It affords a graphic and trustworthy commentary on the statements which we assumed, at the commencement of the session, to have been made in a "missing introductory lecture", but which, from the tenor of all the information which has subsequently reached us, we can hardly venture to hope were really made. That they were well founded and much needed, Mr. Hill testifies from the evidence of his senses, and by an easily acquired experience, which other teachers can, we feel sure, readily command.

The habit of self-gratulation is easy, but it is fatal; and the mutual compliments and felicitations in which students, lecturers, and colleagues of all grades, are self-indulged on the first day of each succeeding October, are to us, and we believe to reasoning beings generally, becoming nauseous, by reason not only of their indigestible sameness, but of their flimsy material. We doubt, and we have reason to doubt, whether there be one course of therapeutics (*materia medica*) given in the metropolis which is fully worthy of the name. We doubt whether there is any school in which sufficient systematic and really complete teaching is afforded to all the students in practical surgical anatomy and minor surgery. There are a few in which practical physiology is being adequately taught—not one in which it is being adequately learned—two very different things. Clinical teaching is still very largely a formula—something which is put down in every prospectus, but which, in the large schools more particularly, only a few students and a few teachers realise. There are one or two schools where all the students are drilled in bedside study, and compelled, by questioning and by alternate spells of duty, to observe and comprehend clinical phenomena. The good example set in this respect by Dr. Hughes Bennett at Edinburgh has extended to some two or three London and provincial Hospitals, but only partially; and in few other hospitals is clinical teaching secured otherwise than partially, fitfully, to favoured or studious individuals, or not at all. It is a common fallacy of hospital teachers to suppose that an occasional clinical lecture, and a few hurried observations as they traverse the wards, realise the requirements of a system of clinical teaching. The result of all this looseness and imperfection in our schools is apparent in the results seen at the examining boards. Many of the ablest lecturers were at one time—and not without reason—much given to saying severe things of the examiners of the College of Surgeons. They had reason; and we have helped to wing the arrows which stimulated those once conservative and retrospective censors of youth to ascend to a higher level, and to join hands with a younger generation versed in the requirements of these later days, and disposed to look steadily at the present, and glance wisely at the future. And now the tables are turned. The accusers are weighed in the balance, and found wanting; and the new tests, light and well-poised as they are, have pierced the weak places of the accusers' armour. This healthy reaction in affairs we wish also to promote. Such aid is the more necessary from us, because the examiners are somewhat tied by official reserve, and are silent

while progress suffers. They are, however, so courteous and so wise as to welcome the teachers at their examinations; and, if all would testify with the same candour as Mr. Berkeley Hill, redress must follow. It is the fact that a large proportion of the students who now present themselves to the College of Surgeons—and we do not doubt that it is the same at the College of Physicians—possess a very low average level of knowledge in some of the most essential respects. A certain proportion of students present themselves who, at the end of four years' study in hospital and school, have learned to point out on the surface of the body the course of the principal arteries, and the spots at which they could be compressed; who can apply a tourniquet, select and use a bandage, manipulate an ordinary dislocation, and dress a wound; who have used the microscope enough to name an ordinary urinary sediment and the normal tissues of the body; who have even also tested urine for albumen, can recognise sugar, and interpret specific gravity; can map out the abdominal edge of the liver, and detect and name a very distinct *bruit*. But these every-day elements of practical knowledge are the possession of a chosen few. The gentlemen across whom Mr. Hill stumbled, who would compress the middle of the thigh-bone with Signoroni's tourniquet for a femoral hæmorrhage, bandage a leg with a rib-roller, and puzzle over the position of the scaphoid in the skin-covered foot, are sadly numerous among those whom the schools send up as finished specimens of their teaching. The result is, that not only are a great many plucked, but the normal standard of examination is perforce dragged downwards. The examiners, brought constantly into a struggle with a dead level of ill-informed mediocrity and imperfectly taught crudity, must perforce condescend to the quality of their material. *Artifex materiem mutare non potest: hæc passa est*. They strive in vain to elicit sparks from the elements of dulness; and at this moment the faults of the schools are reacting injuriously on the spirit of the examiners. We suggested a remedy. Mr. Berkeley Hill, whose experience as one of the earliest and most assiduous teachers of practical surgery in the metropolis entitles his opinion to be well considered, accepts that suggestion, and endorses it. It is far from being novel in conception; nor has it the charm of audacity. But it is simple, natural, tolerably certain in its action: perhaps these are some of the reasons why it has not yet been adopted. Gentlemen who are so much given to the assiduous repetition of self-laudation, as are many of the authorities of our schools, might object to the establishment of data which would disturb the uniformity of gratulation and suggest the necessity of correctives. Our remedy is publicity, that universal panacea of publicists and bugbear of corporations. Let the College of Surgeons and the College of Physicians—let the Conjoint Board of Examiners, when it comes into work—publish tables annually showing the number of students sent annually from each school, the number passed, and the number rejected. Mr. Hill suggests that, for those who pass, it should be indicated by a suitable mark whether they passed very well, well, or fairly. Under the system adopted by the College of Surgeons, and indeed by most Boards of Examiners, this could easily be done; and it would be both just and useful to provincial and metropolitan schools. It would be just, because the merits of those schools which send up a comparatively large proportion of well trained candidates would appear on the face of the returns. It would be useful to two classes of persons—the teachers, who would learn to appreciate the strength and the weakness of their different departments of instruction; and the parents and guardians of students, who could profit by an inspection of results, and to whom the published lists of the Colleges would to some extent and in some respects profitably replace the highly interesting prospectuses and calendars of schools, great and small. Where the promise and the performance did not seem wholly to agree, they might pause to solve the difference. These lists would, it is to be feared, be condemned as invidious. They would occasionally be unpleasant, but then probably the most useful. They would

disturb the spirits of introductory lecturers, and flutter some of the gentle and persuasive pens which indite prospectuses. Now and then a dean of a medical school would have a bad quarter of an hour; sometimes the medical tutor would suffer. But they would have many compensations; and for the thin crust of Paradise, on which they often walk with gingerly tread, would be substituted a more reliable and solid earth beneath their feet. The jays might lose, but the peacocks would bear their bravery more nobly; and, if there be jays, why should they not be stripped? Is any one afraid? We think not. We have never heard such fear avowed. And, if there be none to fear that avowedly useful touchstone, the publication of results, why is it not applied? It certainly will help to improve the coming race of physicians and surgeons.

#### THE REPORTS OF THE MEDICAL COMMISSIONERS WITH THE FRANCO-GERMAN ARMIES.

THESE Reports, much inquired after in Parliament last session, have been produced in a printed volume, having a quasi-confidential character. They are of great interest; and, seeing that they deal with subjects to which free scrutiny from all sources was permitted by the combatants, we may refer to some of the statements made. The Reports are from the pens of Mr. Fitzgerald, D.I.G., Mr. Innes, C.B., D.I.G., Dr. Gordon, C.B., and Surgeon-Major Wyatt.

Mr. Fitzgerald closely summarises the German medical organisation, and compares with it very cautiously, and in facts rather than by comment, our own. The German organisation has been minutely described in our columns, and Mr. Fitzgerald's account testifies to the accuracy of the details furnished by our correspondents during the war. We are very glad to have learned incidentally that the details thus furnished found their way regularly from Berlin through the French territory, and were found useful to more than one of the Government Commissioners. It is unsatisfactory, but of course not surprising, to hear again from Mr. Fitzgerald that we have nothing satisfactory in the way of an ambulance corps, of sanitary detachments, or of *etappen* arrangements. The directions as to the management of flying ambulance stores are stated to be in the crude condition in which they were left by Lord Herbert's Committee, and to be such that the stores could not be packed into the carts; and, if they could be put in, the carts could not carry them. It is quite clear that Mr. Fitzgerald is entirely of the opinion which we ventured to express, upon the strength of Mr. Ernest Hart's inspection of the military organisation of the two armies during the war, that the regimental organisation of the British army is so stiff, inelastic, cumbersome, and costly, that it could not be maintained during war. Mr. Fitzgerald rather leaves this opinion to be inferred, than directly states it; but Dr. Innes and Surgeon-Major Wyatt are more explicit. Dr. Innes speaks quite plainly of the deficiencies of our transport and ambulance system; and Mr. Wyatt states as distinctly that the British medical regimental system, whatever may be its advantages in time of peace, is too cumbersome and costly, too little efficient for the purposes of a campaign, to be upheld under such circumstances. We were sufficiently aware of the unpopularity of these opinions amongst our British army surgeons and assistant-surgeons, who for many reasons cling to their regiments, not to have been cautious in arriving at, and chary in expressing, our conclusions. It is, however, a symptom of coming events, and as such we distinctly intimate that it must be regarded by our military readers and associates, that neither Sir T. G. Logan, Dr. Balfour, Mr. Fitzgerald, nor any other of the eminent officials who were present at the reading of Mr. Hart's paper, expressed dissent from the administrative conclusions; and that the Commissioners with the Franco-German armies appear to be unanimous in their favour. We have, indeed, reason to believe that the project for transmutation has long been under consideration by the authorities; and it may see the light before long. Meantime, a difference in the mode of preparing the *Army Lists* during the last three months, in which the regi-

mental element is somewhat less prominent, appears to be preparing the way for further changes in this direction.

Dr. Innes's Report gives a great number of highly interesting details concerning the German administration. He recommends their elastic scale of dietary (altered during peace, during manoeuvres, and during war), and condemns our own as being relatively less suited for the latter emergencies.

Drs. Gordon and Wyatt had chiefly to study the arrangements of the French army. They condemn unequivocally the system of *Intendance*; but they give a great deal of interesting information as to ambulances, wounds, operations, and diseases, to which we shall again return, comparing it with that collected by Dr. Innes in the hostile camp.

#### THE PRINCE OF WALES.

HIS Royal Highness the Prince of Wales has, we regret to say, been suffering since the thirteenth of this month with feverish symptoms, which have proved to be the commencement of an attack of typhoid fever. This is now the tenth day of the fever, at which date, as physicians are aware, the symptoms are sufficiently precise to afford distinct evidence of the character of the disease (which in the early days has little or nothing distinctive), and to point to the type of the attack. Sir William Jenner and Dr. Gull are both with the Prince at Sandringham. To-night (Thursday) the attack is pronounced to be sharp, but with no unfavourable symptoms. It may be well to recall at once to mind that, in the natural course of the illness and under favourable circumstances, it is likely to run on for yet another eleven days, before the patient can be pronounced to have passed quite through the attack.

DR. T. LAUDER BRUNTON has been appointed joint lecturer on *Materia Medica* at St. Bartholomew's Hospital Medical School.

A NURSE at Sheffield has been committed on a charge of dangerous and gross cruelty to a pauper lunatic in the Eccleshall Union.

MR. A. COOPER has been elected Surgeon to the Royal Hospital for Diseases of the Chest, City Road.

THERE are this year sixty-seven students in the Medico-Chirurgical School of Lisbon. Of these, 19 are students of the first year; 15 of the second; 16 of the third; 13 of the fourth; and 4 of the fifth year.

A PROVIDENT dispensary is in course of formation in Camden and Kentish Town. The rules issued by the Charity Organisation Society will be adopted.

DR. FREDERICK BOND EATON, of Nuneaton, North Warwickshire, was thrown from his trap while returning home on Friday night, and died next morning from exposure to the cold.

SIXTEEN Japanese students have matriculated this year in the University of Berlin. Most of them are attending the medical classes; some are students of jurisprudence and natural science.

DR. ELLIS has been called upon by the Local Government Board to resign his appointment at the St. Pancras Infirmary. The Infirmary has, further, been practically closed, and the patients transferred to the Highgate Metropolitan Asylum.

DR. VON SEYDEWITZ publishes an answer to the charge of making an unauthorised *post mortem* examination, brought against him by Mr. Richards, one of the Deputy Coroners of East London, in a manner which we consider perfectly satisfactory. The Magistrate refused to grant a summons; and it would be advisable for Mr. Richards to offer an apology to Dr. Von Seydewitz.

## LADY MORDAUNT.

WE have reason to know that the statements which have recently been published, to the effect that Lady Mordaunt had been found to have been throughout, and now to be, in a sound state of mind, are opposed to the fact. This unhappy lady is in a diseased state of mind nearly approaching to dementia; and a certificate of her unsoundness of mind, authorising her renewed detention in an asylum near London, was signed last week by Sir James Alderson, the late President of the Royal College of Physicians, and by Dr. Gull.

## ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.

THE fifth anniversary session of this Association is to be held on the 1st and 2nd of December, at the Freemasons' Tavern, Great Queen Street. The anniversary address will be delivered by the President, Dr. Day of Stafford, on Saturday, the 2nd, at 5 P.M.: the subject will be, "The Historical Steps of Modern Medicine." On the previous evening, Dr. Swete will introduce a discussion on "Habitual Drunkenness and its Treatment—Medical and Legislative."

## ROYAL COLLEGE OF SURGEONS.

AT the last examination for the diploma of membership of the Royal College of Surgeons, it is stated that 100 gentlemen appeared, of whom 70 obtained their diplomas; 13 were gentled in surgery, and, when qualified in medicine, will be admitted Members of the College; and 17 were referred to their studies for six months. Of the 100 candidates for membership, 26 had previously obtained other qualifications; viz., L.S.A., 14; M.D. Queen's Univ., 4; M.D. Victoria Coll., Toronto, 1; M.B. Dubl., 1; L.R.C.P. Edin. and L.F.P. & S. Glasg., 1; L.R.C.P. Lond., 1; L.R.C.P. and L.A.S. Lond., 2; M.B. Aberd. and L.S.A., 1; and M.R.C.P. Lond., 1. At the primary examination for the Fellowship of the College, there were 21 candidates; viz., 9 senior Members of the College, four juniors, five who had passed the primary examination for Membership, and three who had not passed any examination. Of the 21 candidates, 12 passed, and 9 were rejected. There were 7 who had obtained the L.S.A.; 2 were L.R.C.P. Lond. and L.S.A.; 1 M.D. St. Andrew's; 1 M.B. Lond.; 1 M.B. Cantab.; and 1 M.B. Edin.

## CHLORAL IN BEER.

BARON LIEBIG lately wrote a letter to a friend in London in which he stated, as a matter of interest, the quantity of chloral that a certain manufacturer turns out weekly. The amount appeared surprisingly great; and the Professor added, as a possible explanation, "Some say it gets into our beer." He probably did not expect that his familiar friend would publish this morsel of unauthenticated gossip. A non-professional journal reads the great German chemist's remarks, and, from small beginnings, the idea has taken shape, and has been extensively repeated in the press in a more or less authoritative form. Dr. Oscar Liebreich, the discoverer of chloral as a medicinal agent, has made a communication to our Berlin correspondent on this subject. He states that there is no ground whatever to suppose that the drug is employed to adulterate beer, and that the public may be at once disabused of this notion. The strong bad taste of the drug fortunately disqualifies it for this nefarious use, and its soporific effects upon the constitution are such as to make it totally unadapted to counterfeit the qualities of genuine beer. The presumed enormous demand for chloral has been authoritatively explained on the ground that the "newest popular vice is to take chloral." Ladies, it has been announced, are especially addicted to it, and it is doing at least as much harm as our old enemy alcohol. The drug is kept in thousands of dressing-cases, and those who begin its use often grow so addicted to it that they pass their lives in a sort of contented stupefaction. One seems to find here evidence of the facile power of generalisation, that writers devoted to social philosophy possess in an eminent degree. If, indeed, so vast a body of women possessing dressing-cases have, within a year or two, come to pass their lives in a sort of contented stupefaction, so astounding a consummation has been brought about without attracting the

notice which it demands. It is just possible that husbands and fathers are so pleased with the contentment and the stupefaction of the ladies, that they have held their peace. In the meantime, it may be well to remember that chloral is used medically, under skilled observation, in the same cases continuously from day to day, and often for periods of weeks and months together, without injury, and the aggregate of all those doses represents a very considerable amount. There are at present no data which indicate its use for other than medical purposes. Such an use would be highly dangerous, and the statements which have been circulated affirming it to exist are mischievous.

## A FEMALE BONE-SETTER.

DURING several months past, one of the most prominent personages in the Austro-Hungarian empire has been a certain Regina Dal Cin, who follows the occupation of a bone-setter. She first learned her business by assisting her mother, who was also a bone-setter, at a small place named Vittorio, in the province of Treviso. After the death of her mother, she joined her brother, who kept a public-house, where she exercised her skill on the lame and crippled frequenters of the establishment, and is said to have effected a number of remarkable cures. Gradually coming into notice among persons of various classes of society, she has obtained a wide-spread reputation, and has visited, among other places, Venice, Trieste, Pesth, and Vienna. In each place, crowds of patients, both belonging to the locality and coming from a distance, have flocked to her. She professes especially to treat deformities of the hip-joint, even reducing dislocations of old standing, whether congenital or acquired. She does not operate except in the presence of a surgeon. This, according to one account of her, is a measure taken for her own safety, as she was once interfered with by the Austrian law, for practising without a legal qualification. We have before us a translation of a document issued by the Royal Commissary of the district of Vittorio, dated July 8th, giving her permission "to practise the reduction of human joints, and especially of femoral luxations, provided that she operates in the presence of a physician or of a surgeon." In her treatment, she first applies poultices for some days, for the purpose of softening the tissues; this having been effected to her satisfaction, she operates by rapidly performed process of manipulation. Professional opinion is divided as to her merits. Her supporters allege that her cures, including the reduction of old dislocations, are genuine; that—as Dr. Schivardi of Milan observes—"science ought to be grateful to her for having amply demonstrated by a vast number of facts—(1) that luxations even of long standing can be cured without recourse to great violence, or to the ponderous instruments hitherto deemed indispensable; (2) that small and modest apparatus suffice after the operation to keep the limb in place—nay, are more efficacious than strong instruments; (3) that quiet and absolute repose for eight days, and moderate repose for other twenty days, suffices to enable nature to bring to the new domicile given to the head of the joint all the materials necessary for the fabrication of the fresh ligaments required." On the other hand, her opponents more or less deny her cures, and some regard her as an impostor. Dr. Neudörfer, apparently admitting some of her cures of ankylosed hip-joint, states that the method which she follows is nearly the same as the process of "apolysis," recommended and practised by him several years ago for the removal of fibrous ankylosis. She has recently paid a visit to Vienna, where her proceedings have attracted a good deal of attention, and have given rise to some degree of controversy in medical circles. On the 4th instant, an officially appointed committee, consisting of Drs. Weinlechner, Lorinser, and Mosetig, accompanied Madame Dal Cin in her visits to four patients. Their report was very unfavourable to her pretensions. The substance of it was to the effect that she has only the most superficial idea of the nature of a dislocation or of the means of reducing it; that in one case she mistook the great trochanter for the head of the femur; that her operative proceedings consist in the performance of purposeless and hasty movements, which can neither reduce a dislocation nor remove a contraction; and that her statements as to the comparative lengths of the

limbs are deceptive. In consequence of the unfavourable nature of this report, the permission to practise in Vienna which had been granted to her has been withdrawn, and she has left that city. She is reported to have gone to Gratz. The information which we have here given is the more interesting, that it is said that Madame Dal Cin is likely to visit this country.

#### THE ROYAL SOCIETY.

THE annual meeting of the Fellows of this Society will be held on the 30th instant. At this meeting, the gold medals of the Society will be awarded to Mr. George Busk, F.R.S., President of the Royal College of Surgeons; and Dr. John Stenhouse, F.R.S. The Copley Medal will be presented to Mr. Julius R. Mayer of Heilbronn.

#### PYÆMIA FOLLOWING TOOTH-EXTRACTION.

An inquest was held at Liverpool, on Wednesday, on the body of a man who had died from pyæmia. It appeared that he had had a tooth extracted three weeks previously, and that the operation was followed by abscess and pyæmia. A similar case occurred at the Middlesex Hospital about two years ago.

#### HEALTH OF THE NAVY.

THE annual statistical report for the year 1869 has just been published. It shows an increase in the death-rate of one per thousand, entirely due to the prevalence of yellow fever on certain stations. On the home station, although there was a slight increase in the ratio of cases of that form of disease against which the Contagious Diseases Act is directed, the majority of the cases were contracted in places to which the Act does not extend. The medical officers, without exception, bear testimony to the value of legislation in this direction, and as a rule advocate its extension. The present volume includes reports on the sanitary condition of the great naval establishments, in somewhat excessive detail, but still including much that is interesting. We shall notice this volume at greater length. The naval reports continue to improve from year to year, under the direction of Sir A. Armstrong and Dr. Mackay.

#### DEATH UNDER THE INFLUENCE OF CHLOROFORM.

ON Tuesday, Mr. Humphreys held an inquest at the London Hospital on Mr. Daniel Ellis, aged 33, who died under the following circumstances. He was an iron merchant, and was superintending the unloading of a quantity of iron, when a piece fell upon his left foot. At the London Hospital, it was found that the first and second toes were fractured. Amputation of the toes was considered necessary. The deceased having undergone the necessary previous examination, chloroform was administered to him; but at first he resisted it, being in a state of excitement. The amputation was proceeded with, when it was found that the pulse had ceased. Remedies were at once used to restore the patient, but life was quite extinct. The verdict was, "Death at the London Hospital, accidentally caused by chloroform."

#### GUN-SHOT INJURIES.

SURGEON-MAJOR WYATT has, by communications addressed to the public press, drawn attention to a supposed neglect by civil surgeons of the study of gun-shot injuries, and a particular superiority of military surgeons in the treatment of such injuries in civil life. In this communication Mr. Wyatt expresses some opinions which are, we believe, peculiar to himself, and which even he would hardly be prepared to support after deliberate reconsideration. Gun-shot injuries receive a large amount of attention in treatises of British surgery. They have nothing mysterious in their character or treatment. The peculiarities of military surgery are mainly related to the necessities of war—transport, aggregation, and supply—as affecting treatment, and not to the mysteries of the injury inflicted by bullet, sabre, or bayonet. Every man is, of course, likely to know most about that which he has most studied, and of which he has had most experience. Hence military surgeons such as Longmore, Muir, and those who have had experience in war,

are leading authorities on the subject. But during peace the military surgeon has chiefly a medical experience, and is more of a general practitioner than a pure surgeon—a very important, honourable, and valuable characteristic. It follows, however, that the average hospital surgeon is frequently a much better authority and more skilled operator, in cases of gun-shot injury in civil life, than the average military surgeon; and this the best military authorities readily admit. The North Germans appointed, during the late war, civil surgeons as the chief consulting authorities in the great army hospitals of the campaign, to supervise and consult with the regimental surgeons in cases of surgical injury. This was going rather far. But it is an instructive commentary on Mr. Wyatt's observations; and the illustrious Stromeyer's translation and commentary on Mr. Mac Cormac's able surgical performances at the civil ambulance at Asfeld complete the lesson.

#### THE CONTAGIOUS DISEASES ACTS.

It has been alleged, since the exertions made in favour of the repeal of the Contagious Diseases Acts, that systematic and efficient examinations have been relaxed, and that contagious diseases are on the increase. In answer to our inquiries regarding these statements, Mr. Milner M. Moore, Resident Medical Officer at the Royal Albert Hospital, Devonport, which affords accommodation under the Act, writes:—"With regard to the amount of syphilis, I may say that there is very little in the town. I do not see a Plymouth prostitute the subject of a 'primary lesion' once in six months, but I do see women with such affections who come from the surrounding unprotected districts, to wit, Torquay, Exeter, Falmouth, Penzance, etc. The Acts here are not being carried out loosely; the women were never in better order as regards appearing for examination, and they behave in a most exemplary manner when in hospital; moreover, our return of those sent to reformatories and friends is now larger than 'it has been for some years. The return from the Commander-in-chief's office for the week ending November 8th shows that out of 8000 men only one was sent to hospital for a local sore. All our disease comes from unprotected districts, and our credit suffers thereby. What will the Government do?"

#### THE HAMPSTEAD HOSPITAL INQUIRY.

WE read with pleasure the following resolution, which seems to us as just as it is graceful. It was unanimously agreed to, at a meeting of the Committee of Management of Hampstead Hospital held since the close of the inquiry. "That the Committee desire to express to the Medical Superintendent, Dr. Grieve, to Sister Frances, and to the sisters and nurses under her charge, their sympathy with them under the unmerited imputations made against them of negligence in the discharge of their duties at this hospital. The Committee cannot but feel that the long and searching inquiry into the management of the hospital has abundantly proved that the grateful thanks of the Committee are due to the medical superintendent, sisters, and nurses, for their untiring labours, watchfulness, and skill, in the treatment and nursing of the sick entrusted to their care during the recent severe epidemic of small-pox."

#### FOREIGN PRACTITIONERS IN PORTUGAL.

THE session of the Society of Medical Sciences in Lisbon was opened on October 28th, with an address by the President, Dr. Barbosa. He took as his theme the regulations under which the holders of foreign diplomas and degrees are allowed to practise medicine in Portugal; giving, in the course of his address, an outline of the regulations on the subject in force in the various countries of Europe. In Portugal, under a law passed in 1861, all foreign practitioners desiring to practise are obliged to pass the same examinations as those educated in the country; but they are exempted from the necessity of attending a curriculum. There are three institutions authorised to grant diplomas—the schools of Lisbon and Oporto, and the University of Coimbra. In the two former, eleven examinations are required, each of which occupies a separate day. At the present time, a Dutch gentleman, who wishes to

practise ophthalmic surgery in Lisbon, is undergoing a course of these examinations, which commenced on October 17th, and will end on December 7th; there being an interval of five or six days between each two examinations. The subjects are anatomy, physiology, materia medica, external pathology, operations, midwifery, internal pathology, clinical medicine, clinical surgery, legal medicine and hygiene, and pathological anatomy. These examinations having been passed, a thesis has to be written and sustained. At Coimbra, only five examinations are required. Dr. Barbosa suggests that professors in foreign schools of acknowledged repute, should be admitted to practise in Portugal on their titles being verified by a jury of professors from the medical schools of the country; and that other practitioners should be admitted on passing certain examinations, after having presented a diploma from some licensing body of not inferior reputation to any in Portugal. The examinations should comprise anatomy, materia medica and therapeutics, midwifery, operations, practical medicine, and practical surgery; and should conclude with a thesis. Dr. Barbosa believes that, by the plan which he proposes, merit would be duly recognised, and the precautions necessary for the safety of the health and life of the people would be established.

#### PROGRESS OF CHOLERA.

FROM a daily record of deaths during the month of October now before us, we find that 654 deaths from cholera were recorded at Constantinople in the last twenty days of October, the number of deaths on the last day being 46. The sanitary state of Hasskeni, in which the English were confined by the abominable device of the "sanitary cordon", may be gathered from the statement which our correspondence includes, that "the foul pool of putrefying blood and offal is still disinfected; the open drain rolls its foetid stream down the populous slope into the Horn; and all the conditions which foster cholera are in full activity in the village." Sir H. Elliott seems to have done the best for his countrymen.—Our latest dates from St. Petersburg show 16 or 20 cases under treatment, and no deaths reported since Oct. 21st.—Regulations have been made by which all persons arriving at the port of Smyrna from places where cholera exists are liable to ten days' quarantine on a barren island about twenty miles from the port; and, it is stated, without due provision having been made for the proper care of the persons so detained.—At Helsingfors, in the week ending October 7th, there were 18 cases of cholera and 15 deaths; in the week ending October 14th, 10 cases and 3 deaths; from that date to October 18th, 2 cases and 1 death. The total number of cases since the commencement of the epidemic was 300; the deaths were 165.—Cases of cholera are reported to have occurred at Medina.

#### THE SALE OF DIPLOMAS.

THE *Boston Medical Journal*, referring to the scandalous sale of diplomas which has long been carried on by a bogus establishment called the "American University of Philadelphia", states that so wide spread is this contemptible and now unlawful traffic, that the officers of the University of Pennsylvania are fairly persecuted with letters of inquiry from Europe and from this country concerning these advertisements and applications for the supposed sale of its degrees. Of course, any one who really knows anything about that school knows that it would be as easy to buy the moon as to buy a degree from the University of Pennsylvania. But the "University of Philadelphia" so closely resembles it in name, that the trick is easily played; and the authorities of the genuine University of Pennsylvania have at last, in self-defence, found it necessary to set forth the following circular as an answer to all applications for its honorary degrees. The circular embodies not only the regulations of the University, but the law of the State of Pennsylvania, which makes this traffic in diplomas a misdemeanor, with a penalty of fine and imprisonment.

"University of Pennsylvania, Philadelphia, September 1871.—Frequent applications are made to the authorities of this University by gentlemen who desire to obtain honorary degrees. As these applications are made in evident ignorance of the rules which govern the Uni-

versity in conferring these degrees, as well as the law of the State of Pennsylvania on the subject, it has been thought best to reprint the existing regulations.

"Extract from the Statutes of the University.—Of Honorary Degrees in Divinity, Law, Arts, and Medicine.—1. These may be conferred either at the instance of the Faculty, or in pursuance of a resolution of the Board of Trustees; but no such degree shall be conferred unless the *mandamus* ordering the same be signed by two-thirds of the whole number of trustees, nor unless the candidate shall have been nominated at the Board three months previously to taking the question on conferring the degree. 2. The question on conferring an Honorary Degree shall always be decided by ballot, and the candidate must receive an unanimous vote.

"An Act to prohibit the Sale of Academic Degrees.—Section 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same, That it shall not be lawful for any University, College, or other institution incorporated under the laws of this State with power to grant Academic Degrees, honorary or otherwise, to confer the same upon any person or persons upon the payment or promise of payment by any person in consideration thereof; and any person knowingly signing a diploma or other instrument of writing purporting to confer an Academic Degree when such consideration has been paid or promised to be paid, shall be guilty of a misdemeanor, and, on conviction thereof, be sentenced to pay a fine not exceeding five hundred dollars, and to undergo an imprisonment not exceeding six months, or both, or either, at the discretion of the court. Approved May 19th, 1871."

#### SCOTLAND.

DR. JOHN RAE, the Arctic explorer, delivered a lecture in the Philosophical Institution on Tuesday, on the two expeditions to the Arctic regions.

A NEW lunatic asylum was opened last week for the Barony Parish at Lenzie Junction, near Glasgow. It will afford accommodation for four hundred patients. The site on which it is to be built extends to one hundred and seventy acres, and has been purchased at a cost of £10,000. The grounds will thus be larger than those of any asylum in Scotland. It is stated that they are rich in minerals, and will in large measure cover the expenses of the building in a few years.

#### SMALL-POX IN CABS.

DR. W. T. GAIRDNER of Glasgow, in an admirable letter to the *Scotsman*, calls attention to the practice of conveying cases of small-pox to the Edinburgh Royal Infirmary in cabs; and this too frequently from localities quite beyond the municipal boundary, and from which cases should not be sent at all. Such a state of things, he urges, may be easily remedied, provided that Edinburgh is thoroughly prepared for its own obligations as regards conveyance of the infected sick by means of specially constructed and regularly disinfected vehicles for the purpose. He proposes that it should be made known as widely as possible, through an official notice to the newspapers, that every case in which patients suffering from infectious diseases are brought to the Infirmary in cabs is watched by the authorities, with a view to prosecution under the Public Health Act. Under this Act, Portobello has no right whatever to empty out its small-pox cases upon Edinburgh, by means of common cabs. On the contrary, like all other towns, it has, by the provisions of the Act, to provide proper accommodation for its own cases; and as this may be done in three weeks, by constructing an iron hospital, the sooner the fact is made known and acted upon the better. Dr. Gairdner, very properly, protests against the indiscriminate admission of infectious cases into the Infirmary, while an Act may be put in force to compel the local authorities to do their duty by affording accommodation for their own cases. As small-pox is again on the increase in the city, and the City Hospital has been, in consequence, again opened, the Infirmary Managers may well undertake at the present moment the consideration of the whole question of the admission of infectious cases.

## IRELAND.

DR. SPOTTISWOODE, at Cahirciveen, has been called upon by the Poor-law Commissioners to resign for neglecting to attend to a red ticket at night. The *Guardians*, we are glad to hear, will request the Commissioners to withdraw their decision.

A COURTEOUS and handsomely illuminated address of thanks has been presented to Dr. Morrison of Newry, in testimony of the satisfaction of the Managers of the Rathfriland Road Hospital at his successful exertions in the conduct of the institution.

A DUBLIN Surgeon writes to the *Irish Times* to say that he regards the recent manifesto of Sir James Paget and his *confrères* "as an assumption of superiority on the part of the London profession which, though kindly meant, is yet uncalled for."

DR. HANAFIN has been charged by the Rev. B. O'Connor, P.P., with neglect of his duty as a physician in a midwifery case. The Commissioners entirely approve of Dr. Hanafin's conduct, and regret that the Rev. Mr. O'Connor took upon himself to interfere.

## REVACCINATION.

BUT for the neglect of revaccination—almost as important as vaccination—small-pox could have gained no foothold whatever in Dublin. Revaccination is now, however, steadily progressing; nearly seven thousand persons have been revaccinated by the dispensary doctors during the last three months. The clergy of all denominations are urging the revaccination of the children of the various schools; it is also advancing amongst the upper classes. We have not been able to discover the slightest bad result, beyond, perhaps, in a few instances, some slight temporary inconvenience.

## EXHUMATION OF TALBOT.

WE are glad to say that we have received communications from some of the most eminent army surgeons, emphatically assenting to the opinion which we stated to be universal amongst civil surgeons, that Mr. Stokes's treatment of the case of Talbot was quite in accordance with the most advanced rules of surgery. Amongst those who have expressed this opinion to us is Professor Longmore, C.B., the most eminent British authority on gunshot wounds. He emphatically endorses the opinion that the death of Talbot was solely due to the pistol-shot wound. In relation to this bullet, we may observe that there is a tolerably wide-spread opinion that, under the peculiar circumstances of the verdict, and of the subsequent statements from the jurors, it would be proper to order the exhumation of Talbot's body, with a view to a search for the bullet, which is supposed, from the published records of the *post mortem* examination, to be still lodged in the body. Its examination would throw light upon the "slug" hypothesis which has been started; and it is still important to clear up all the facts.

## DUBLIN OBSTETRICAL SOCIETY.

THE opening meeting of the thirty-fourth annual session of this Society was held on November 18th, in the Hall of the College of Physicians; Dr. G. H. Kidd, President, in the Chair. There was a large attendance of members of the profession. The Report for the past year was read and adopted. It stated that the Society was making most satisfactory progress; and it was announced that arrangements had been made for the regular publication of the transactions and discussions. The President delivered an address on "Recent Advances in Obstetric Science", in which he entered at length into the question of the instrumental treatment of tedious and difficult labour, illustrating his remarks by statistics based on the practice of the Rotunda Lying-in Hospital during the past eighty years. Dr. Joseph Clarke, who was master from 1787 to 1793, used the forceps but once in each 728 cases. As a

contrast, in the three years during which Dr. G. Johnson has now been master, he has employed the forceps once in 14.74 cases. The mortality of the mothers after tedious and difficult labours has fallen from 20.21 per cent. in Clarke's time, to 7.38 per cent. of the present; and of those delivered with the forceps, from 50 to 6.86 per cent. Again, of children born by the aid of the forceps, the mortality had in the same period fallen from 50 to 4.9 per cent. That the use of the forceps was the cause of vesico-vaginal fistula, Dr. Kidd believed to be quite unfounded; on the contrary, this unfortunate accident generally resulted from not using the instrument. Though the use of the perforator and the practice of embryotomy had recently been reduced to a minimum, great advances had been made in the construction of the instrument required in the performance of this operation. In another class of labours, that of transverse presentations, mechanical skill had also done much to overcome most serious difficulties. In the treatment of *post partum* hæmorrhage, again, great improvements had been introduced. Laceration of the perinæum might be remedied in some cases by a judicious application of sutures. Lastly, where the uterine discharges after labour became foetid and putrid, Dr. Braxton Hicks had successfully washed out the cavity of the uterus with a solution of permanganate of potash. In conclusion, Dr. Kidd thanked the members for having again placed him in the presidential chair. Dr. Stokes moved, and Mr. Darby seconded, that the President's address be printed. The resolution was carried. On the motion of Dr. McClintock, seconded by Dr. Ringland, a vote of thanks to the Presidents of the Colleges of Physicians and Surgeons, to the Governor of the Apothecaries' Hall, and to the other visitors present for their attendance, was passed. The President then declared the result of the ballot for the election of officers to be as follows: *President*—George H. Kidd, M.D. *Vice-Presidents*—J. A. Byrne, M.B., and H. J. Sibthorpe, M.D. *Treasurer*—H. O'Hallahan, L.K.Q.C.P. *Honorary Secretary*—L. Atthill, M.D. *Council*—J. Denham, M.D.; T. E. Beatty, M.D.; A. H. McClintock, M.D.; and F. Churchill, M.D.

## SMALL-POX IN DUBLIN.

THE present outbreak of small-pox in Dublin is assuming a very serious aspect. The deaths are not numerous, because vaccination has been so thoroughly carried out that the disease, as a rule, assumes a very modified form, but the number of persons attacked is very great. As might have been anticipated, the disease has now extended to the upper classes, and several deaths from it have taken place amongst them during the past week. The spread of the disease is attributed in many instances to the fact that there are no conveyances to bring cases of infectious or contagious disease to hospital but the public cabs. The only hospital that possesses a cab of its own is Cork Street Fever Hospital, which is now virtually closed, not having room for any more cases of small-pox. The Corporation, though empowered to provide vehicles, have done nothing except fine a cabman, who probably could not afford to defend himself. A more sturdy opponent, an ex-policeman, in Bridgefoot Street, whose case has been weekly before the public for the last three months, and who is described by the magistrate as having "shown every opposition he possibly could to the Corporation," now threatens to bring them into the Queen's Bench. This case might have been summarily settled in one fortnight from the date of the first summons. The consequence of this neglect of their duty, by the sanitary authorities, if such there be, is, that small-pox is at present so widely disseminated that children but a few weeks old, and in consequence not vaccinated, come into contact with it; and in a very short time, no doubt, every individual who has either not been vaccinated, or who has been imperfectly vaccinated, will contract the disease. As the Corporation are so very apathetic in this matter, is there no body sufficiently interested in the welfare of the city as to bring the matter before the Lord-Lieutenant? It might perhaps come within the province of the College of Physicians; and the able paper read by Dr. Grimshaw last week must have turned their attention in that direction.

## CASES OF SKIN-GRAFTING.

IN a paper published in the *Proceedings of the Medical Society of Upsala* (vol. vi, part 4), Herr C. B. Mesterton describes the operation of skin-grafting, and relates several cases which had come under his care. For the translation, we are indebted to Dr. J. W. Moore of Dublin.

CASE I.—D. J., a cartwright, 41 years of age, on December 11th, 1870, received a charge of shot through the left arm, just above the elbow-joint. He was admitted to Hospital on the 14th. After several grains of shot, pieces of wadding and clothes, and sixteen splinters of bone had been removed from the wound, it was dressed, and daily washed out with an antiseptic lotion. The arm was totally split across immediately over the epiphysis, so that two fingers could be pushed straight through the limb, and the injury appeared, regard being had to the close proximity of the elbow-joint, and to the probability of fissures into the articulation, to indicate immediate amputation. A trial of the antiseptic treatment was nevertheless made, under which the wound took a very favourable turn. There was but little swelling; no redness either above or below the sore; no fever; the appetite was good; there was very slight pain, and favourable suppuration. Granulation was active and healthy; during its course, sixteen more splinters of bone, several grains of shot, and portions of wadding were removed. Six weeks after his admission, the large sulcus of the wound was filled up, and the sore was successfully healing. On February 9th, two portions of skin, each a little larger than a lentil, taken from the arm, were transplanted. When the wound was inspected on the seventh day, the uppermost layer of epidermis came away with the strapping, but in other respects the pieces of skin had entered into organic union with the bottom of the wound, firmly adhering to it, and they had also sunk rather beneath the surface of the granulations. A number of fine vessels gave a lively bright-red appearance to the patches, which were covered by a thin transparent epidermis. On February 24th, the epidermis-formation had so far advanced from the engrafted pieces of skin, that a bridge running right across the sore had become developed.

CASE II.—Charlotte Ericsson, aged 18, was admitted on October 16th, 1870, having had her left forearm crushed in a threshing-machine. Both radius and ulna were fractured, the muscles and tendons were torn, and the skin was completely detached from the entire internal aspect of the forearm. The patient opposed the proposal to amputate, in consequence of which the crushed limb, with fragments of bone sticking out here and there through the torn muscles, was simply laid on a splint and covered with an antiseptic dressing. Some partly gangrenous tissue was thrust off; and after this, the case, without any intervening accidents, went on to a relatively favourable termination. In the end of January of the present year, the numerous fractures had united, while the cicatricial formation in the soft parts had made considerable progress. The great loss of skin on the inside of the forearm made it easy to foresee, however, that the healing process would be extremely protracted, if indeed possible. In this situation, two pieces of skin taken from the back were transplanted on January 31st, with the same favourable result as in the former case. These two cases show, also, the good effect of the antiseptic treatment. In both, early operation was apparently indicated; yet the mode of treatment adopted was successful in rescuing the injured extremities with—at least in the first case—a great degree of usefulness; no irritation worth mention showing itself in the neighbourhood of the wound during the whole period of recovery, nor any suppurative prostration, nor even any disturbance of the patient's general health.

CASE III.—C. R. Anderson, aged 23, a servant, was admitted on the 2nd of March, 1870, for varicose ulcers of the legs. They were treated by means of poultices, diachylon ointment, and Baynton's bandage. Under these, the sores repeatedly healed, but, after a few days, again broke out. On March 13th, a tolerably thin patch of skin, so large as almost to cover one of the ulcers, was excised with a bistoury, and transplanted. When the bandage was removed on the fourth day, the piece of skin was found universally adherent to the bottom of the ulcer, and traversed by a number of fine vessels. Three days afterwards, the entire ulcer had healed, and then presented in the centre a firmer and brighter epidermis than at the edges of the sore, where the cicatrix was thinner and more livid.

CASE IV.—A. W. Ovarnstrom, aged 47, a servant, was admitted December 13th, 1870, for varicose ulcers of the left leg. They were treated by poultices, diachylon ointment, styxan ointment, and solution of caustic. On February 18th, a piece of skin about the size of a sixpence was removed from the arm with a straight bistoury. A very shallow incision was made, so that little more than the Malpighian

layer came away. The patch of skin was placed in the middle of the ulcer, about three square inches in size, and secured by strapping. After seven days, it was found firmly united; and, from its edges, new epidermis was formed, so that the healing process in the middle of the ulcer, after two weeks, engaged three times as large a surface as the engrafted piece of skin. On March 6th, a new transplantation was tried on another ulcer, which miscarried; on removal of the strapping on the fifth day, the piece of skin came away in a sloughy state. On March 23rd, the operation was repeated with a similar bad result. The rather indifferent state of the sore, and the fact that the knife was moistened with water, were probably the causes of the failure.

CASE V.—P. Pettersson, aged 64, formerly a farmer, was admitted February 15th, 1871, for an ulcer of the left leg, about five inches in length and breadth. The dirty, partly sloughy, sore was treated by poultices, and washing with dilute carbolic acid; after eight days, it assumed a healthy appearance, and the edges began to heal. On March 3rd, eight patches of skin, excised partly from the back, partly from the arm, were engrafted on the superior half of the ulcer, and Baynton's bandage was subsequently laid over the whole sore. On the 9th, the bandage was removed; five of the pieces of skin had undergone organic union with the subjacent granulations, forming small, highly vascular patches, in close contact with the surrounding granulations, and on a level with the newly developed epidermis from the edges of the ulcer. The remaining pieces of skin had formed yellowish-white, pus-infiltrated, soft patches, elevated above the surrounding tissue, but yet tolerably firmly adherent to the granulations. On the inferior portion of the ulcer, three pieces of skin, excised with a straight bistoury, were the same day engrafted, and Baynton's bandage was again applied. When the bandage was taken off on March 16th, not a trace of the last transplanted, very thin patches of skin appeared. From the five former pieces of skin, on the contrary, a very active formation of epidermis was seen going on. Four of these were already united by bridges of epidermis to the superior edge of the ulcer. The other three, infiltrated with pus, had completely disappeared. Three patches of skin cut off from the back were again engrafted, and the same bandage applied. On March 21st, they were also found in a state of mortification. The transplantations had thus, on the last two occasions, completely failed—a result which was supposed to depend on the relaxed spongy appearance which the ulcer had assumed during the last two weeks. Warm poultices and repeated touching with caustic were therefore again employed to excite activity in the granulations. On April 3rd, when the ulcer had once more taken on a healthy aspect, a fresh engrafting was performed with one piece of skin—thinner and larger—cut off by a knife, and with two snipped off by scissors. The patches were placed straight across the ulcer, the first mentioned between the other two. The ulcer, in its entirety, had at the time diminished to about the size of a crown-piece; its upper part, where the first engraftings were made, had perfectly healed two weeks before. On April 6th, the bandage was opened, when the centre patch was found sloughed, the remaining two living and abundantly supplied with vessels. Subsequently, the epidermal formation spread out from them on all sides.

CASE VI.—Beda Charlotte Ericsson, aged 21, was admitted to hospital February 17th, 1871, for periostitis and tuberculous ulcers of the left leg. Iodide of potassium was given internally, and the sores treated by poulticing until they presented healthy granulations. On March 10th, a patch of skin from the back was transplanted. Some days afterwards, all trace of this was thought to have disappeared; but afterwards, on March 23rd, a newly formed island of epidermis was seen rising at the spot where the transplanted piece of skin had been applied. The process of healing subsequently went on without interruption.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Mr. George Hanbury, of Portman Square, has accepted the office of Treasurer to this old established charity, in the vacancy occasioned by the decease of Mr. John Savory. The hospital has been in existence nearly one hundred and twenty years.

BEQUESTS, DONATIONS, ETC.—Mr. John Barrow, of Westbourne Terrace, has bequeathed £4000 to build an Infirmary within five miles of Southwell, and £6000 for the support of it.—Miss Mary Colton, of Cambridge, has bequeathed her "residuary estate" to Addenbrooke's Hospital, Cambridge.—The Worcester Infirmary has received £100 under the will of Mr. Benjamin Birch Davies, of Broadwas.—The Glasgow Royal Infirmary has received £100 under the will of Mr. William Brown, jun., of Salrecoat.—Mr. Alexander Findlater has given £100 to the Convalescent Home, Stillorgan, near Dublin.—Messrs. Storey Brothers and Co. have given a second £105 to the Royal Albert Asylum, Lancaster.—The Northampton General Infirmary has received £135 under the will of Mrs. Maria C. Johnson.

## ASSOCIATION INTELLIGENCE.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE next meeting will be held at the General Hospital at Maidstone, on Tuesday, November 28th, at 4.15 P.M.; Dr. ALBERT DAVIES in the Chair.

Dinner will be provided at the Mitre Hotel at 6 P.M.

*Business to be transacted.*—The election of a member of the Medico-Ethical Committee of the district, vice Joy, resigned.

FREDERICK JAMES BROWN, M.D., *Honorary Secretary*.  
Rochester, November 13th, 1871.

### EAST YORK AND NORTH LINCOLN BRANCH.

THE next quarterly meeting of the above Branch will be held at the Hull Infirmary, on Tuesday, December 5th, 1871, at 4 P.M.; J. A. LOCKING, Esq., President, in the Chair.

ROBERT H. B. NICHOLSON, *Honorary Secretary*.  
21, Albion Street, Hull, November 18th, 1871.

## SPECIAL CORRESPONDENCE.

### BERLIN.\*

[FROM A CORRESPONDENT.]

*Effect of the War on the University.*—*Female Students.*—*The Scientific Meetings and Professor Virchow.*—*Virchow on the Advantages of Association.*—*New Books.*

IN his address at the opening of the present University Session at Berlin, the outgoing Rector quoted some interesting figures showing the effect of the recent war on the activity of the University. In Oct. 1870, there matriculated in all the faculties 1,236 students, while the number of entries for the winter session of 1869 was 2,421. Of the 1,236 students who entered their names in October, only 904 continued their attendance throughout the winter. The actual number of medical students last winter was 173, while in the previous winter session they amounted to 550. The falling off in numbers extended about equally to all the four faculties; but it appears that none of the theological students who entered at the beginning of the session were required to break off their studies. The courses of lectures, public and private, that were announced amounted to 366, and of these 271 actually came off. Forty students took their degrees—8 in jurisprudence, 19 in medicine, and 13 in philosophy. The number of deaths, so far as was ascertained, amounted to 32. The University seems now to have returned to its full activity, to judge from the crowded state of many of the classrooms. A few of the students are to be seen wearing the ribbon of the Iron Cross.

Two ladies from America have applied to the Berlin University authorities for permission to attend the medical classes. One lady, a Russian, is studying chemistry in Professor Hofmann's laboratory. An American lady has been studying medicine at Breslau, and has sent to an American newspaper a glowing account of her friendly reception at the Silesian University. Another pioneer of the same sex is studying engineering at the Polytechnic School of Aix-la-Chapelle; and two ladies recently joined the University of Prague, where they are studying under the professor of history. During the past summer a solitary American lady, M. D., attended the clinics at the Vienna General Hospital, and appeared to suffer, to the full extent, the inconveniences of being in so considerable a minority.

The autumn season on the Continent, as in England, is marked by the occurrence of various scientific gatherings. At several of these, Professor Virchow has been receiving ovations, which the Berlin newspapers have chronicled from time to time. At the Assembly of German Naturalists and Physicians, held at Rostock, his speech was the great event of the meeting. During the Bologna Conference of Archæologists, he was entertained at a banquet by the Italian dignitaries and men of science; and at a scientific assembly held in Rome, the audience rose to their feet to welcome the celebrated Berlin professor, who made them a speech in French. In his address to the Rostock Conference, Virchow made some remarks upon the nature of annual scientific

gatherings, of which he himself is an assiduous frequenter. "It was a matter of encouragement to me," he said, "when I read in the proceedings of the recent meeting of the British Association, in the opening address of its renowned President, Sir William Thomson, that Brewster, in his letter by which he called the Association into existence, expressly stated that he was led to this step from considering the great and beneficent results that the German Naturalists' Association (*Naturforscherversammlung*) had achieved during its nine years' previous activity. We were the first to advance among all nations; the English followed, and the number of these associations has gradually increased. They have, by degrees, extended into every possible province of human activity, and we have thereby become accustomed, by the co-operation of the many, to define more clearly the common objects at which the whole has to aim." And again, speaking of the results of these meetings, he says: "Not only the pleasures of fellowship, which are inseparable from a great congress of individuals; not only the amenities of personal acquaintance, which cannot be too highly valued; the forming of friendly ties, where perhaps, under other circumstances, harsh and even bitter opposition would have sprung up; the reconciling of many controversial antagonisms through personal intercourse—all this is the smaller result. There is yet a greater—the communication of knowledge, the explanation of methods, the clearing up of the directions in which research should be undertaken—and these are things which can be nowise better told than by word of mouth." The main subject of Professor Virchow's address was the part that science would have to play in the new national life of Germany. Their work, he held, was to introduce into the popular life of the nation the great and all-pervading idea of evolution. Space will not permit even to give an abstract of his views.

Among the books that have issued from the German press within the last month or two are—the new edition of Virchow's *Cellular Pathology*, much improved and enlarged; Professor Traube's *Contributions to Physiology and Pathology*, in two bulky volumes, one containing experimental and the other clinical researches; a new instalment (the fifth) of Stricker's *Handbuch*; a treatise on Leuchæmia, by Professor Mosler of Greifswald; and an elaborate work, with plates, by Barkow of Breslau, on *Dilatations and Tortuosities of the Blood-vessels*, with special reference to aneurism of the aorta in its various sites.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 14TH, 1871.

H. A. PITMAN, M.D., Vice-President, in the Chair.

ON THE OPERATION OF OPENING THE LARYNX BY SECTION OF THE CARTILAGES, ETC., IN ORDER TO FACILITATE THE REMOVAL OF MORBID GROWTHS. BY ARTHUR E. DURHAM, F.R.C.S.

THE author related in detail five cases in which this operation had been performed in Guy's Hospital: in three cases by himself, in one by Mr. Bryant, and in one by Mr. Davies-Colley. The results in four of these cases had been eminently satisfactory, free respiration and good voice having been regained. The remaining case was still under treatment. Appended to the communication were more or less complete reports of all the cases which the author had been able to find on record. These cases were thirty-two in number, and, with the five detailed in his communication, gave a total of thirty-seven. In nineteen of these, the operation might be regarded as having been completely successful, natural respiration and voice (though in some instances not normal in tone) having been restored. In seven, partial success was obtained, respiration having been restored, but the voice lost or very seriously impaired. In four cases, some temporary relief was obtained. In three, the result might be considered negative, neither good nor harm having been done. The reports of at least two were incomplete. In two cases only, death resulted. In each of these, however, the immediate cause was blood-poisoning. Metastatic abscesses were found in the lungs in one case; in the other, erysipelas and gangrene occurred, and broncho-pneumonia and exhaustive fever ensued, and led to the fatal issue. Comparing the results thus stated with those given by Dr. Mackenzie in his treatise on Growths in the Larynx, the author pointed out that death could properly be attributed to the operation in two only out of the nine cases enumerated by Mackenzie as having terminated fatally, these two being the same as those already alluded to. With regard to the other seven cases, the author specified each, and showed that in each the result of the operation was favourable, or, at any rate, in no degree mischievous, and certainly not fatal. Some of the diffi-

\* This letter was unavoidably omitted from our last issue through pressure of matter. See page 576 of that number.

culties liable to be encountered in the operation were then briefly discussed, and the opinion was expressed that such difficulties were really fewer and more easily overcome than appeared to be generally supposed. In conclusion, the author pointed out that it was not necessary to institute any comparison between the dangers and difficulties of this operation and those met with in the removal of growths through the mouth by the aid of the laryngoscope; nor, indeed, was it at all fair to estimate the comparative merits of the two methods of proceeding by bare numerical statements of the results obtained. If, in any case, removal of the growth by aid of the laryngoscope should appear practicable, the idea of resorting to section of the cartilages could not be entertained until fair trial had been made of the minor operation. In very few, if any, of the cases on record in which the larynx was opened, would it have been practicable to remove the growths through the mouth. Indeed, in many instances, numerous abortive attempts through the mouth were made before resort was had to section of the cartilages. With regard to the chances of recurrence, there could be no doubt that the more completely the original growth was removed, the less would be the probability of its reappearance. Neither could there be any doubt that such complete extirpation could be more certainly effected in most cases after section of the cartilages than by any method practised through the mouth. Dr. Mackenzie's conclusions as to the comparative chances of recurrence, as affected by the method adopted, appeared to the author unfair and likely to mislead. Cases of cancer (a malady very likely to recur) were included in one, and excluded from the other, of the sets of cases between the results of which a numerical comparison was made.

Mr. BEYANT considered that Mr. Durham had shown the operation to be worthy of attention on the part of surgeons. The operation in the cases described had been performed only because no other means could relieve the patients; tracheotomy, indeed, might have prolonged life for a short time, but the capital operation alone could save it. In cases of simple growth, this effect might be expected to be permanent; in cases of malignant growth, we could expect to prolong life only for a time. With regard to the operation itself, the great object was to bring the parts well into view. He was startled at hearing that the evidence on which Dr. Morell Mackenzie opposed the operation was of a very weak kind; there being, in his nine cases of death, seven where he could not see how the fatal result could be ascribed to the operation. He hoped to hear an explanation from Dr. Mackenzie. Even admitting that death had been caused by the operation in nine cases out of twenty-two, this would be scarcely a fair ground for condemning the operation. He regarded the operation as most valuable; though, of course, no surgeon would perform it if any other means were available for prolonging life.—Mr. HOLTHOUSE had performed one of the earliest operations of the kind described, in March 1864. The patient was a lady, to whom he was called by Dr. Gibb to perform tracheotomy. On the following day, he enlarged the opening upwards, and removed a number of mucous growths from the interior of the larynx. The patient recovered her voice, and retained it for several months after the operation; she died at the end of a year from extension of the original disease.—Mr. THOMAS SMITH asked whether, in closing the wound, it was necessary to fasten the margins of the thyroid cartilage together, or were sutures through the integument sufficient.—Dr. PITMAN remarked that Mr. Durham's five cases were in patients under 10 years of age; in Dr. Mackenzie's cases, 96 in 100 were above that age.—Mr. DURHAM said that in children the removal of laryngeal growths through the mouth was difficult, on account of the narrowness of the passage and the restlessness of the patients. No doubt, in the adult also, the growths were removed in this way in some cases, after all other means had failed. The amount of suffering produced by the removal of the growths through an opening in the larynx was much less than that which attended repeated operations by the mouth. He regretted much that Dr. Mackenzie was not present. He had informed him of his intention on that evening to take exception to some of his statements.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, NOVEMBER 1ST, 1871.

J. BRAXTON HICKS, M.D., F.R.C.P., President, in the Chair.

*Imperfect Involution of the Uterus.*—Dr. SNOW BECK exhibited an imperfectly involuted uterus, and described its microscopical characters. He arrived at the following conclusions. 1. The elements of the different tissues retained a portion of the natural enlargement consequent upon impregnation; but the enlargement was due more to the increased size and amount of the soft tissue in the walls of the uterus, as well as at the internal surface, than to the increased size of the contractile fibre-cells. 2. Although the blood-vessels were large and loaded

with fluid blood, yet there was no evidence to show that any morbid process, similar to inflammation, had at any time been present. 3. The whole of the blood-vessels, to the minute capillary network at the inner surface, formed one continuous system, though the character of the distribution changed towards the inner surface. This distribution appeared to offer a strong argument against the idea that the internal surface could be the seat of inflammation independently of the other portions. 4. The pulpy condition of the tissue at the inner surface, with the loaded state of the blood-vessels throughout, appeared to afford a probable explanation of the frequent hæmorrhages which attended similar enlargements. 5. With regard to treatment, this should include topical applications to the whole of the uterine cavities.

Dr. F. R. HOGG exhibited a Malformed Fœtus. It was referred to a Committee.

*Osteomalacia.*—Dr. BARNES read an abstract of a memoir on osteomalacia, by Dr. CASATI of Milan. This disease is remarkably frequent in some of the rural districts surrounding Milan. During the eight years that the author had acted as assistant to the late Professor Lazzati, sixty-two cases of clearly marked osteomalacia were admitted into the Lying-in Hospital. Almost all the sixty-two women came from that part of Milan known as the valley of Olona, the same district which also supplies the greatest proportion of cases of pellagra and of petechial typhus to the Milan hospitals. They all came from wretched villages where food was scarce, consisting, for the most part, of maize or rice, often musty. Their houses were ill-ventilated, damp, and built upon clay. The drinking-water was found wanting in saline matter. Twenty-seven of the women were delivered normally after easy labour, four had difficult labour, while thirty-one were delivered artificially, but only two required the Cæsarean section. For the medical treatment, Dr. Casati recommends the use of the biphosphate of lime or of "bone-powder," and cod-liver oil, and the substitution of Liebig's bread for bread made of rice and maize.—Dr. SQUIRE did not agree with the author that the pulmonary and bronchial congestions afforded any argument against the use of chloroform, since these depended on the mode of death; and, in severe labours, the use of chloroform tended to diminish the stress upon both respiration and circulation.

*Treatment of Uterine Flexion.*—Dr. RASCH read a paper on a novel method of using the uterine sound for redressing a flexed uterus. The part of the instrument inside the uterus should be kept steady in its place, so as to avoid irritation. The sound introduced into the retroflexed womb, with the point downward and backward, should be first used in that position as a lever to lift up the organ as far as possible. Then the movement should be reversed, so that the part in the uterus and its ideal prolongation are made the centre of motion, round which the handle and stem sweep.—Dr. PHILLIPS would be glad to know the comparative frequency with which it was found necessary to use the sound for redressing the reflexed uterus. Doubtless it could not be dispensed with in some cases; but he always attempted to restore a retroflexed uterus without the introduction of any instrument, and he believed that in a large proportion of cases this could be effected.—Dr. GUSTAVUS MURRAY could hardly admit that the method described by Dr. Rasch was new. He had employed it for some years.—Dr. AVELING and Dr. EDIS also said that they had practised the method. Dr. Edis said that Spiegelberg had recently called special attention to the danger resulting from the injudicious use of the sound.

*Prolapse of the Female Genitalia.*—Dr. CONRAD, of Pesth, read a paper on prolapse of the female genitalia. He maintained that prolapse of the uterus was, for the most part, a secondary affection. Prolapse of the vagina was the most important part in any descent of the female genitals, and uterine prolapse was but a sequel—the prolapsed vaginal walls pulling down the uterus. Of the different forms of vaginal prolapse, that of the anterior wall was most common, though frequently associated with prolapse of the posterior wall. A descent of the latter by itself was rare. Should there be a considerable elongation of the cervix, it might be certainly concluded that the vaginal prolapse was primary. The elongation of the vaginal portion of the cervix was of no diagnostic value, and was simply the result of mechanical irritation. Dr. Conrad believed that elongation of the supravaginal portion of the cervix and hypertrophy of the infravaginal portions were but secondary affections. The most important predisposing causes of prolapse were gestation, parturition, senile atrophy, etc. Prolapse in young girls occurred suddenly from a sudden shock through *contrecoup*. The replacement of a complete prolapsus of long standing should always be preceded by an emptying of the bladder and the rectum. The palliative treatment was best conducted by pessaries, of which the best was Meyer's ring, or Hodge's modification of it. For the radical cure, Dr. Conrad preferred Spiegelberg's operation. The vaginal portion of the cervix uteri, if greatly hypertrophied, was first removed by the galvanic wire. If the posterior wall of the vagina had become pro-

lapsed with the uterus, he performed Dieffenbach's operation by removing a triangular piece of the mucous membrane of the posterior wall, having its apex to the os uteri, and for its base either the pared surfaces of the rent perineum, when this had been ruptured, to form a new perineum, or, where this had not happened, the labia minora, so as to contract the orifice of the vagina, and aid in supporting the anterior vaginal wall. Spiegelberg then united the upper portion of the posterior vaginal wall with the inferior anterior, according to Simon's operation.—Dr. EDIS thought that the affection, on account of its great frequency, was too little studied. He had seen cases where a pessary had been introduced with the intention of keeping up an elongated cervix.—Dr. PHILLIPS said that certain cases of prolapsus uteri were doubtless secondary to vaginal prolapse—cases in which the uterus was small. He believed that this class was a much smaller one than that where an increased weight of the uterus itself was the primary cause of its descent. This was associated with relaxation of the surrounding areolar tissue. The arguments brought forward by M. Huguier seemed to him conclusive against the view advocated by Dr. Conrad, that elongation of the supravaginal portion was a secondary affection. He doubted whether any shock would produce displacement of the uterus in young women if the organ were not increased in weight, and there existed no impairment of the surrounding structures.—Dr. HEYWOOD SMITH agreed with what had been said, that the chief cause of prolapsus uteri was an increased weight of the organ producing relaxation of its supports. Another cause, however, was not generally recognised; viz., that as age advanced, the lumbo-sacral curve becoming more or less obliterated, the plane of the pelvis thereby becoming more horizontal, the natural support that the normal position of the pelvis, together with the abdominal walls, gave to the pelvic viscera was removed, and they tended to prolapse from gravitation.—Dr. ROUTH believed that prolapsus uteri without elongation of the cervix was very rare. His own experience led him to agree with the conclusions arrived at by Dr. Conrad. For the relief of prolapsus there were three chief methods which had been practised. First, there was the perineal operation. Secondly, Emmett's operation, or Dr. Rogers's modification of it, consisted in the removal of a large triangular piece of mucous membrane from the anterior, or sometimes from the posterior, wall of the vagina, and bringing the edges together by sutures. Both these operations succeeded in some cases, though not in all. Thirdly, came the plan of removing a portion of the cervix by the *écraseur* or actual cautery. This set up absorptive action in the uterus, and the elongation in many cases gradually but entirely disappeared. Dr. Routh thought that a cure, to be certain and radical, should comprise the three operations conjointly, or, at any rate, the last and one of the other two.—Dr. BARNES said that for some years we had all been pursuing a tentative course to find out the best mode of treating these affections. As to the mode of production of hypertrophy, he was scarcely prepared to agree with Spiegelberg and Dr. Conrad. The traction of the vagina might come in as a factor in the course of the disease, but the initiatory stage was, he believed, congestion and increased weight of the uterus. These cases were rare in women who had not borne children. The passage of the child through the cervix was a violent process: the cervix was forcibly stretched open; the mucous membrane was carried down before the head; the tissues of the cervix were bruised; small vessels were torn. Then, from getting about too soon and other causes, imperfect involution resulted, the lower part of the uterus especially was increased in weight and bulk, whilst the surrounding cellular tissue, having been greatly stretched and weakened, was less able to support the uterus. Hence continued congestion and perverted nutrition of the cervix. Small polypi on the edge of the os frequently complicated hypertrophy. Their structure was identical with that of the cervix from which they sprang. Dr. Barnes could not help thinking that simple prolapsus was far more frequent than Dr. Routh's observations would indicate. He would like to know how far the experience of others agreed with his own as to the usual extent of elongation being exactly five inches. He had found the cases in which this length was exceeded very rare.—Mr. SPENCER WELLS differed from Dr. Barnes in the opinion that restoration of the perineum was beginning at the wrong end in the treatment of prolapsus of the uterus and vagina. Prolapse of the anterior wall of the vagina was the first step in the progress downwards. But a sound perineum was the chief opponent to this prolapse. It would be absurd to expect the perineal operation to cure an elongated cervix; but in cases of ordinary prolapse, the perineal operation often effected a permanent cure. He had never seen an elongated cervix grow again after the vaginal portion had been removed.—The PRESIDENT said that when the uterus, from whatever cause, descended, by its pressure on the vagina, it acted like a foreign body and set up reflex irritation and tenesmus, which acting constantly, coupled with defecation and the pressure of the bladder, would tend to extrude and elongate the cervix.

It would clearly be better, before attempting any plastic operation, to endeavour to gain shortening of the uterine supports, either by pessaries or by recumbency.

## MEDICAL SOCIETY OF LONDON.

MONDAY, NOVEMBER 6TH, 1871.

ANDREW CLARK, M.D., F.R.C.P., President, in the Chair.

*Rhinoplastic Operations.*—Dr. LICHTENBERG communicated two cases of rhinoplastic operation. The patients, two females, were shown. He did not bring them forward as models of the plastic art, as he was far from being satisfied with them, but to show that much might be done by the surgeon in such cases. Mrs. K., the first of the two patients, had been for some time under treatment at the German Hospital, for tertiary ulceration of the nose; and, being discharged cured, was sent to him. On examination, he found that the septum, the entire left ala, and also almost the entire right ala, were destroyed. She was admitted into the Tottenham Training Hospital. On March 23rd, 1871, he took two flaps from the forehead; but, believing that he could not obtain a sufficiently large flap without encroaching considerably on the scalp, he merely formed the two alae, with the intention of providing the septum from the upper lip at a future time. He found, however, that the nostrils, or rather the nostril, contracted so much that he did not consider it warrantable to produce a new deformity, with the doubtful prospect of a tolerably good septum. The second case came under his treatment in the Tottenham Hospital, and was useful in showing what large doses of iodide of potassium could do in these particular cases. Directly this remedy in large doses was given, the improvement was well marked, and the ulceration rapidly healed. He waited some months to see whether the disease was thoroughly subdued, and operated on April 6th. The whole nose, with the exception of some rudiments of nasal bones, was destroyed. He had to form a very large flap from the forehead; but the skin contracted more than he anticipated, and he thought that in these cases the flap could scarcely ever be too large, provided it could be made without creating a larger deformity.—Mr. FRANCIS MASON said that when the pedicle was taken from the centre of the nose, the supply of vessels was scanty. Was the flap applied to a raw surface or an ulcerating one? In a case at the Westminster Hospital he had made three small flaps, one above the aperture, and the others from each side of it, turned these over the opening, and laid the flap forming the nose, and taken from the forehead, over them. After the patient's discharge, some slight ulceration had taken place at the tip of the nose. The nose was now broader and not so symmetrical as those shown.—Mr. W. ADAMS, Mr. DAVY, and Mr. DE MÉRIC also joined in the discussion.

*Urethral Rheumatism.*—Mr. THOMAS BOND read a paper on so-called urethral rheumatism. This was not the effect of any specific poison or constitutional diathesis; and it often occurred quite independently of gonorrhoea, as well as of very gouty or rheumatic predisposition. It was dependent on a local condition of the urethra; and he called it urethral rheumatism as being the most convenient name. It occurred in men of an anæmic or weakly condition, or when gonorrhoea had been treated too long by copaiba or purgatives. There was a subacute inflammation of the synovial membranes and of the fibrous tissues about the ankles, heels, and balls of the great toes; it gradually affected the shoulders, elbows, and hands. Congestion of the sclerotic was present; and the health suffered severely. Exacerbation took place, with pains in the loins in the morning, followed by profuse perspiration, with loss of appetite and of sleep. The urine was scanty, the tongue coated, the face hectic. The limbs often became permanently contracted, unless great skill and care were used in the treatment. The urethral discharge varied from profuse muco-purulent discharge to the slightest gleet fluid. The disease was not diathetic but septæmic; in fact, a chronic pyæmia. He believed that the altered state of the blood was kept up by the daily absorption of the morbid materials from the urethra. As soon as the supply of the *materies morbi* from absorption was stopped, the blood gradually eliminated the poison and returned to its healthy state. The peculiar immunity of women was owing to the greater thickness and coarseness of the vaginal epithelium than that of the male urethra, and to their not being treated by specifics and antiphlogistics. If the disease were a rheumatic urethritis, and not an urethral rheumatism, why should not women be equally liable with men? Antiphlogistics, copaiba, and iodide of potassium did no good, but rather harm. The proper treatment was full diet, with steel and quinine wine, and porter, and lastly injection, until the discharge was completely cured. A very good injection was tannin and opium with water.—A discussion took place, in which Mr. ADAMS, Mr. BRUDENELL CARTER, Mr. DE MÉRIC, Mr. DAVY, and Dr. A. CARPENTER took part.

# MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

WEDNESDAY, NOVEMBER 15TH, 1871.

ALFRED HUDSON, M.D., President, in the Chair.

*Fever in Dublin.*—Dr. W. GRIMSHAW read a paper on the prevalence and distribution of fever in Dublin, a full account of which appears at page 605.—Dr. HENRY KENNEDY alluded to the existence of fever as a disease among most divisions of the vertebrata, and feared that, despite all the efforts made, epidemics could never be stamped out. Visitations of this kind he looked upon as beyond human control, at least to a large extent.—Dr. C. F. MOORE quoted Dr. Letheby's opinion that the purest water was not always the best suited for drinking purposes—a statement which might apply to the Vartly water, now extensively used in this way by the poorer inhabitants of Dublin. He believed, too, that the report of the contamination by sewage of the Roundwood reservoir of that water, was in some measure founded on fact. The south side of New Row, a street which ran through the lowest part of the Coombe Valley district described by Dr. Grimshaw, was built over the Poddle River, which thus acted as a tolerably well-flushed drain; and the result was a markedly diminished prevalence of fever in the houses in that situation as compared with those on the north side of the street.—Dr. JAMES DUNCAN observed that the general deterioration of health which took place in ill-drained houses, was an evident cause of increased susceptibility to the action of different poisons on the part of the inhabitants of such houses. As to the law of the usual progression of epidemics from east to west, he suggested that its explanation might possibly depend on the diurnal revolution of the earth on its axis in the opposite direction.—Dr. STOKES would ask, What was the end of sanitary reform? In his opinion, we could not look forward to the complete destruction from amongst us of the causes, be they what they may, of epidemic diseases, as the necessary effect of the action of a perfect sanitary code. It would be more reasonable to consider the beneficial results, which would doubtless follow the full development of hygiene in all its bearings, as depending rather on an improved state of the national health. The human system would, under such circumstances, be in a better position to resist epidemic influence when it approached; and, where an individual had already become affected by it, he would be able to bear up with more success under the particular disease from which he happened to suffer.

## CORRESPONDENCE.

### CANDIDATES AT THE COLLEGE OF SURGEONS.

SIR,—A few evenings ago I was enabled, by the courtesy of the President, to be present at the *visd voce* examination in Surgical Pathology and Practical Surgery at the College of Surgeons. I was very favourably impressed by the mode of conducting the examinations; but the material to be tested was certainly much inferior to my expectations. I was introduced into the large theatre of the College, where the Court received the candidates in batches of four, each man being taken in hand for ten minutes by two examiners, who led him to a live model stripped, and asked him most elementary and obvious questions on surgical anatomy—for example, the proper place to apply a tourniquet to the femoral artery in amputation of the thigh. It was painful as well as ludicrous to see a candidate, after glibly repeating the points to be observed in order to secure compression of the artery, when told to select a tourniquet and put it on, take a Signoroni and manage to place it halfway down the limb, in such a way that by no possibility could the compress be brought to bear upon the vessel; or, again, as did another candidate when requested to bandage a leg, take a four-inch wide roller, and, blind to the kindly hint of the examiner that he had better try a narrower bandage, persist in using it, until, after two or three failures, he was obliged to acknowledge that he could not bandage a leg. Of course I do not know whether these gentlemen passed, or were referred to their studies for six months; but I sincerely trust the latter alternative was their fate. A third gentleman was utterly unable to point out the situation of the scapula or the fifth metatarsal bones in the foot, though exceedingly ready to amputate in an imaginary and not very severe injury to that member. Indeed, so embarrassed are some of the candidates, that the authorities wisely put wooden amputating knives into their hands, lest the luckless model, in an excited moment, be shorn of his fair proportions. When their knowledge—in too many cases ignorance—of practical surgery had been tested in bandaging, putting on trusses, etc., on the living model,

the candidates were taken by a second pair of examiners, for another ten minutes, to patients having some obvious surgical malady, to give a diagnosis and suggest the appropriate treatment. The blunders made were past conception; and the novelties in treatment suggested were often as surprising. One gentleman proposed to cut a cancer out of a man's tongue with a scalpel, having, as his only resource against probable hæmorrhage, some solution of perchloride of iron.

Throughout this wearisome occupation, I observed none of the examiners show impatience or want of anxiety to draw out any bit of knowledge the students might possess; and the satisfaction these gentlemen displayed when, as now and then was the case, the candidates proved well able to answer the questions put to them, was pleasant to witness.

On the whole, the examination struck me as being extremely well planned, and by no means an easy one for a simply crammed student to get through. I could only regret that the average level of practical knowledge among the candidates was so low, that the examiners seldom ventured to put any question of serious difficulty.

The suggestion made in the leading article of the BRITISH MEDICAL JOURNAL of October 7th, *à propos* to the advice annually given to students beginning their medical studies, came forcibly to my recollection—namely, that the Council of the College of Surgeons should publish more detail of the causes of failure at their examinations. If an analysis of the candidates' proficiency in the several departments were published, stating the number of gentlemen from every school who passed well, moderately well, or badly, in each subject, the teachers would be made aware of the weak points in their system of instruction. Of course, at every good school, the aim is not simply to "get their men through the College", but to make the students proficient, and to train them in habits of observation and reflection, that, when more advanced, the young men may in their turn contribute to our store of knowledge. If each teacher at the end of the year were made aware of the way in which his pupils had passed the ordeal at the College, he would have the honest satisfaction at reading a good report, or the opportunity of knowing that, to gain success, he must modify his exertions in certain particulars. It appears to me that, were such information set before the teachers at medical schools, the amount of knowledge now necessary to let a man through the College would be rapidly increased; and the recipient of the member's diploma would ere long have the satisfaction of knowing that his qualifications had been fairly tested, and that he had gained a certificate of proficiency in surgery, instead of, as the case now is, having been only proved to possess the smallest modicum of surgical knowledge which it is deemed safe to let him use in practice. It is with the hope of keeping the attention of medical teachers on this point, to which you have already adverted, that I have troubled you with this letter.

I am, etc.,  
London, November 1871.

BERKELEY HILL.

### WATER-THEORY OF CHOLERA.

SIR,—In reference to your summary of Dr. Cunningham's conclusions regarding the water-theory of cholera, given under the head of "Lessons from India", in your issue of November 18th, permit me to point out that Dr. Cunningham's main argument on the subject, and the only one that calls for any remark, is based on an entire misconception of the facts of the Peshawar epidemic. In paragraph 39 of his paper published at page 263 of the sanitary blue-book for 1871, he writes as follows: "The main water-supply is the small stream which runs through the cantonment, and which is very liable to defilement; but the water from Mackeson's well is of good quality, and from this was obtained what was required both for the 104th Regiment and the Artillery. The 36th Regiment drank of the stream-water; and yet they did not suffer more than the wing of the 104th which remained in the cantonment after the other wing left, and drank of the well-water." Now the fact is, that the wing in question did not remain in the cantonment at all, and that it was in camp at Chumkunni when cholera attacked it with epidemic virulence. I take the proof of this assertion from Dr. Cunningham's sixth Annual Report, in which, at para. 134, he writes as follows: "The right wing, numbering 278 men and 17 officers, unhappily was much less fortunate. On the 13th September, one case occurred among them. On the 14th, there was one; on the 15th, two; on the 16th, one. On the morning of the 17th, they marched to Chumkunni; and on that day, after arrival in camp, there were four cases of cholera. On the 18th, there were fifteen admissions. Next morning they moved two miles off, to some rising ground. This 19th was their worst day, twenty-seven soldiers having been attacked on it."

Chumkunni was suffering from cholera when the troops arrived

there; and, just as at Peshawar, the water-supply was mainly obtained from surface-cuts exposed to every kind of pollution.

It is clear, therefore, on Dr. Cunningham's own showing, that so long as the wing remained in cantonments, the cases of cholera were few—not more numerous, in fact, than might be expected, when the state of the water-supply in the station generally is borne in mind; and also that, whatever water may be provided for the men in barracks, they must drink, when away from barracks, whatever water they can get; and, with a thermometer near 100 deg. F. in the shade, soldiers are not particular what they drink. The native population, who took their water-supply mainly from the filthy cuts that traverse the station in all directions, were suffering very severely at the time. On their march to Chumkunni, the troops must have drunk largely from surface-cuts of a like description; for the population of that portion of the Peshawar valley have frequently no other source of supply. I submit, therefore, that Dr. Cunningham is not justified in stating that “the London experiment has indeed been tried in Peshawar, but with a very different result. Here also we have different sections of the community living under similar conditions in every respect except the source from which they drew their water-supply; but there has been little difference in the extent to which they have suffered from cholera.” Indeed, the very reverse of this is the fact; for the officers and others, who were careful about the water they used, drinking mostly good water, escaped with comparatively little loss.

Differences of opinion in the interpretation of facts are inevitable; but the facts themselves should be beyond dispute.

On the general question of the water-theory of cholera, I will only add that, after a careful examination of the available records of the Punjab epidemics and of the localities affected there, I have not found a single instance in which the water-supply was not palpably subject to gross contamination; and, on the other hand, I have found that, in several stations which suffered severely, a bad water-supply was the only sanitary defect of importance discoverable.

I am, etc., A. C. C. DE RENZY, Surgeon-Major.  
Kingstown, November 1871.

#### MORTALITY OF LIVERPOOL: A SECOND PEABODY.

SIR,—I beg to be allowed to draw an exception to some remarks in the last number of the JOURNAL regarding “the coming shower of gold”—remarks wherein the public are led to believe or suppose that Drs. Parkes and Sanderson have demonstrated to the learned and sanitary Town Council of Liverpool, that the *fons et origo* of our excessive mortality over other towns is the excessive intemperance which prevails among the working and lower classes.

Doubtless it is necessary for experts to say something when they are called upon to explain phenomena which have baffled our local *savans*—to lay hold of anything rather than confess themselves beaten; but allow me to remark that, if the “back slums” of Liverpool be any worse in this respect than the districts of St. Giles, Seven Dials, and the east end of London; if they be any worse in this respect than the east end of Glasgow, or the Cowgate, High Street, Canongate, and the wynds and closes of Edinburgh; if they be worse in this respect than Dublin, Belfast, or Cork, Manchester, Birmingham, Newcastle, Bristol, Southampton, or Portsmouth—let them prove it! I, for one, do not believe that our excessive intemperance bears any relation whatever to our excessive mortality, the cause of which, I hold, has still to be found out.

While pointing out the supposed cause, Drs. Parkes and Sanderson have failed to prescribe the only reasonable remedy. There is only one method of cure for the excessive intemperance of the working classes, and, like many excellent cures in this world, it is very difficult of attainment by or for the poor—and that is, lessening the hours of manual labour; giving the working man a greater interest in his labour and a more just equivalent for his services; providing him with the means of cultivating his higher and nobler nature, his manhood, by affording him the leisure and means of cultivating an acquaintance with nature, with science, with art, literature, poetry, with his fellow-creatures everywhere, and with all things which develop the inner man and which tend to raise him above the mere animal. Only think what we ourselves would be without adequate education, without leisure, without science and literature as the substance, and without books the embodiment of them, without music, poetry, and refined society. We would be much the same as those whom we are so ready to condemn; and, until we have provided the working classes with a national education in the proper acceptance of the term, with free

schools, with feeding schools, as much as possible free from every form of sectarian influence; and until we have lessened the hours of manual labour, afforded more leisure and means for intellectual and moral improvement, and used every means within our power of developing a taste for such pleasures or ways of happiness—we may talk, we may theorise, we may moralise and sermonise on the depravity and intemperance of the working or manual class, and condemn them. But all this is in vain, for we only expose our own intense but pardonable ignorance; we are merely temporising and moralising upon the effect, the intemperance of an overwrought and too much neglected class of our fellow-creatures—the wealth-creators—instead of divining and removing the cause of their intemperance.

Before the second edition of Mr. Peabody reaches the public, or before the worthy and intending donor commits himself and his £500,000 to the tender hug and delicate handling of those who deal in bricks and mortar, I would advise him to take a leaf out of my portfolio. Instead of investing in bricks, let him make bricks of men, and out of the raw material, men and women with developed souls in their bodies, who will, in process of time, reward him by building houses of their own from the interest accumulated by the industry of their own hands and the tear and wear of their own brains, aided primarily by the judicious application of so magnanimous a gift as half a million sterling. Providing for the wants of the poor is the surest way of pauperising them. Teach them how to think for themselves, and how to provide for themselves, and the excessive intemperance of Liverpool, and of the land, yea, of the whole family of man, will be a thing that was.

I am, etc.,

THOMAS SKINNER, M.D.

Dunedin House, Liverpool, October 16th, 1871.

#### SEWAGE AND ENTOZOA.

SIR,—I observe in your article on Australian Entozoa that, at a late meeting of the Royal Microscopical Society, Dr. Cobbold used terms somewhat to the effect that, “while on swampy ground, as about Croydon and other low-lying districts, where this mode of irrigation was practised,” etc.

Surely Dr. Cobbold has never visited Croydon, or he would be aware that it is neither “low-lying” nor “swampy”. There is nothing like a swamp in any part of the parish. It mainly consists of chalk, with a superstratum of sand or gravel, except at the northern part of the parish, where it meets the edge of the London and plastic clay. At this part, which is the lowest, and close to the western boundary, the river Wandle finds its outcrop. The river runs thence downwards through Beddington upon a chalk and gravel bottom to the Thames. This outcrop, which is the lowest part of the parish, is 140 feet above high-water mark at London Bridge. On the north, the streams called Effra and the Ravensbourne get their tiny springs, which also run downwards to the Thames. Dr. Cobbold has probably been misled by the biased evidence of Mr. Hope, who, curiously enough (though Croydon had won its successes in sewage-irrigation before Mr. Hope was heard of, except as the type of a courageous Englishman), never reads a paper without asserting something to the detriment of Croydon. We are quite aware that our plans are not perfect, for perfection does not belong to human works; but I wish again to give publicity to two facts. First, I have carefully watched for evidence to bear out Dr. Cobbold's theory. If I had found it, I should have published it at once. There is no more evidence now than there was two years ago, when I contradicted Dr. Letheby's deductions at a meeting of the Association of Medical Officers of Health. Secondly, the five hundred acres of irrigated land under our indirect supervision (not in the parish of Croydon) continue to be entirely free from the least particle of evidence that they promote either the distribution of entozoa or the production of enthetic disease. We have frequent returns of the state of health in that district; and during the past half-year the deaths have been at the rate of ten to twenty-seven births; and, with the exception of a case of scarlatina which occurred on a hill more than a mile away from the fields, there is not a single death which can be referred to ordinary removable causes.

It is not necessary to contradict the innuendoes frequently cast out by those who are probably searching after truth as well as myself (though occasionally associated with promoters of a patent); but, when they have the support derived from being quoted in our JOURNAL, I think a correction should be given.

I am etc.,

ALFRED CARPENTER, M.D.

Croydon, November 20th, 1871.

# THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

## DR. STALLARD'S STATEMENT AS TO LUNATICS IN METROPOLITAN ASYLUMS.

SIR,—I find that a statement, which is supposed to have been made at the Holborn Board of Guardians, has been interpreted to mean that sane persons have been admitted, and are kept, at Caterham Asylum; and that they have been sent thither by the parochial medical officers, for the sake of a fee of £1:1, to be received for certifying. The latter part of the statement would be so well known to be contrary to fact by the gentleman to whom it is attributed, that I cannot believe he made it. Every one at all conversant with Poor-law administration in the metropolis knows that no fee is received for certifying patients to Caterham or Leavesden Asylums, or for any action whatever connected with them.

That, among the seventeen or eighteen hundred patients sent to the Caterham Asylum during the past twelve months, there were a few who were not proper subjects, is true. Some were liable to paroxysms of violence, and were therefore more suitable for a county asylum, whither, as their cases develop themselves, they are sent. Had the medical officers been anxious to secure the fee, they would have sent these patients to a county asylum at once, in which case they would have received a guinea. A few of the cases have been discharged cured, and therefore were not, strictly speaking, proper cases for this asylum, as, according to the Act of Parliament, no dangerous or curable cases are to be admitted. Until, however, the Act of Parliament provides some infallible means of diagnosing the curability of such cases, I think that the medical officers must continue to send them. This, however, is something quite different from the statement alluded to, which, whether reported correctly or not, requires contradiction. There are no sane cases in the asylum, unless one or two have had their cures completed since the last (fortnightly) meeting of the committee, in which case they will have been discharged before this letter appears in your columns.

I am, etc.,

WILLIAM S. CORTIS, M.D.,  
Chairman of the Committee of Managers of the Metropolitan  
Asylum, Caterham.

141, Kennington Park Road, November 20th, 1871.

## PAUPER LUNATIC CERTIFYING FEES.

SIR,—In your Poor-law Medical Service article of the 18th instant, under the head of "Fees for Certifying to Pauper Lunatics" you say, "... the fee is fixed by the magistrate or justice of the peace before whom the case is investigated." But the case of a pauper lunatic is not always or necessarily investigated before a magistrate or justice of the peace. The "order for the reception of a pauper lunatic (Sched. F., No. 1)" gives as the authorised committees or senders, a justice of the peace or magistrate, or, "a clergyman and relieving officer or overseer." I am moved to point this out to you, possibly because this very event happened to me no later than last week; and, though I am sure the Board of Guardians will in this case raise no objection to give me my fee, yet I ask you to be good enough to inform me and my confrères how we should legally enforce its payment if the guardians refused to grant it.

While on the subject of lunatics, I may perhaps be allowed to mention that the clerk to that Board of Guardians, whose servant I am, informed me, no later than yesterday, that in future I must send all lunatics to the workhouse in the first instance, as there was an order to this effect—authority unknown, but either Local Government Board, or the Superintendent of the County Asylum. The reason also is (very unfortunately) unknown; but it is supposed to be either for the benefit of the lunatic or of the medical officer of the workhouse.

Will you kindly inform me whether it is not within my province as district medical officer to decide the destination of my patient—whether he is fitter for the asylum than for the workhouse?

November 19th, 1871.

W. H. CREIL TESSIER, M.D.

\*.\* The respective duties of the relieving officer and the medical officer of either a workhouse or district with respect to the certification of pauper lunatics are clearly expressed in the Act of 16 and 17 Vict., cap. 97. It is the duty of the medical officer to give notice in writing to the relieving officer of the union containing the parish to which the

pauper may be chargeable; and such relieving officer must take the requisite proceedings. It is not sufficient for the medical officer verbally to inform the relieving officer or the master of the workhouse, or to enter the case in his book. The Act 16 and 17 Vict., cap. 97, sect. 67, imposes on the relieving officer the duty of causing lunatics to be removed to asylums. In order to avoid the excitement and often painful scenes occurring through the public examination of pauper lunatics in police-courts, the Poor-law Board, on the recommendation of the Lunacy Commissioners, issued a circular letter in 1867 to guardians of the poor, urging them to provide some justice, having proper jurisdiction, to attend at the workhouse or the home of the supposed lunatic, to hear and investigate the case. When a justice cannot be found to attend, a clergyman of the parish and a relieving officer may be applied to for this purpose. The Poor-law Board, however, consider that this latter plan is undesirable, and should not be adopted unless there be very strong necessity; and then due care must be taken that proper medical assistance is rendered in the case, and that the investigation is so conducted that no doubt may arise that the order has been issued after full deliberation, and with all necessary regularity. The examination of pauper lunatics before a magistrate is the rule; and only under very exceptional circumstances is it done before a clergyman. In the very few instances where the lunatic is examined before a clergyman acting in the place of a justice, the Act does not expressly confer the power of fixing and ordering the payment of the fee by the clergyman. If he be also a justice, he, of course, can make the order. It is, of course, open to the medical man to refuse to examine, if he be in doubt as to whether he will be paid for his services or not. The district medical officer has not to decide whither a pauper lunatic is to be sent. This depends upon the settlement of the pauper and the order of the magistrate. The Lunacy Commissioners, through the Poor-law Board, have expressed a strong opinion against sending pauper lunatics to workhouses or retaining them there. On the grounds of economy and humanity, acute cases of lunacy are best sent directly to an asylum, where they can have all the advantages of systematic care and treatment from the onset of their malady.

## STIMULANTS IN WORKHOUSES.

SIR,—The table of expense per head for stimulants, and the average of deaths in certain workhouses, published in your issue of November 4th, appears intended to convey the notion that the deaths are in direct proportion to the supply of liquors, and, *vice versa*, that the longevity is proportionate to the deficiency of stimulants, would seem to be the case if some of the instances be taken; as, for instance, where the highest expenditure corresponds with the greatest death-rate. In almost all other instances, however, the figures tell in the opposite direction; for instance, at West Derby, the cost per head is 5s. 6d., and 1 in 11 die; and if 3d. per head more be spent, as at Lambeth, only 1 in 17 die. Take, again, Glasgow, where, at 9d., the deaths are 1 in 11. It will also be seen from the statement given below, that twopenny more gives the lowest death-rate of the whole series. Liverpool, cost per head 1s. 5d., 1 death in 12; Charlton, cost 1s. 8d., 1 death in 14; Leeds, cost 11d., 1 death in 18; Birmingham, cost 10d., 1 death in 20; Aston, cost 1s. 9d., 1 death in 27; Crumpsall, cost 10d., 1 death in 38. There must be some factor of importance beyond the administration of stimulants, that has been omitted in the consideration of the causes of the different percentages of mortality.

I am, etc., S. C. S.

A PUBLIC VACCINATOR writes:—I think it very objectionable that, in appointing Vaccination Officers under the new Act, preference should be given to relieving officers. They are too much under the dominion of the anti-vaccination portion of the Board of Guardians to properly perform their duties in respect of enforcing vaccination. I trust that your influence may cause the matter to be taken up by the local Government Board.

\*.\* We shall be glad to hear from other correspondents on this subject.

## OBITUARY.

### PHILIP CHILWELL DELAGARDE, F.R.C.S.,

Senior Surgeon to the Devon and Exeter Hospital and Exeter Eye Infirmary; President of the South-Western Branch of the British Medical Association, etc.

MR. DELAGARDE died at his residence, Southernhay, Exeter, on the 17th November, 1871. He was the son of the Rev. Philip Delagarde, sometime Rector of St. Martin, Jersey, and of Sarah, the daughter of Jonathan Chilwell, Esq., of Westerham and Hadlow in Kent. He was born at Chelsea in 1797, and there his father died when he was a year old. He was an only child, and passed his early years with his mother in the neighbourhood of Exeter. Mr. Delagarde received his classical education at the Exeter Grammar School during the time that Dr. Lempriere (also a member of a Jersey family, and the author of the *Classical Dictionary*) was its Master. On leaving school (1813), he became a pupil of Mr. Sydenham Peppin; and in 1816, on Mr. Peppin's death, of Mr. Samuel Barnes. As their pupil, he enjoyed the advantages offered by the Devon and Exeter Hospital, of which they were both surgeons. He thence proceeded to St. Bartholomew's Hospital, where

he studied under Abernethy and others; and, during the final year of his residence in London, was the resident House-Surgeon. He became a member of the College of Surgeons in 1819.

In 1820, he took up his residence in Exeter, styling himself "surgeon-oculist", and commenced general practice. He was early elected one of the three medical officers to the Corporation of the Poor. He soon acquired an extensive practice amongst the wealthy families of the city. In 1836, he was appointed Mr. Barnes's coadjutor at the Eye Infirmary; and henceforth became deeply interested in the practical details of ophthalmic surgery. He had already (1820) published a treatise on *Cataract*. He was an advocate, as was Mr. Barnes, for the cure of cataract by absorption and depression, and never resorted to extraction until within the last two years. He then adopted the linear incision of Von Graefe's operation, but preferred to open the capsule before making the section of the cornea, and sometimes removed the lens with a scoop without removing any iris, with a result equal to that of the flap-operation as to regularity of pupil. He showed to the members of the Association, at the last branch meeting in Exeter, a patient on whom he had performed this operation with very good result.

In 1841, on the death of Mr. S. Luscombe, the senior surgeon of the Devon and Exeter Hospital, he was elected Surgeon. He had long been ambitious to occupy the position and fulfil the duties of a Surgeon; and he repeatedly regretted that he was so far advanced in life (43) before he succeeded to the public exercise of these duties. Until then, there had been no vacancy in the surgical staff of the hospital for twenty-five years.

In 1845, he was selected as one of the hundred and fifty first Honorary Fellows of the Royal College of Surgeons.

He was a good anatomist and operator. Though his hand was perhaps less delicately expert than it might have been, had he from early life practised operative surgery, yet his self-confident and well-established knowledge rendered him a safe and successful operator. His opinion was ever felt to be such as could be relied on. He was an assiduous and careful observer of modern surgical progress, and always adopted such of the new suggestions in practice as appeared to him beneficial. His last operation was in furtherance of conservative surgery—the resection of a knee-joint. He practised midwifery reluctantly; and ever maintained that it would be a good thing for the profession to be disembarassed of it.

In the exercise of his profession, he was conscientious and painstaking, and, for the good of his patients, neglected no effort. For the poor who were under his care, whether in the Eye Infirmary or the County Hospital, his first and chief solicitude was shown. At times, there was perhaps a hasty manifestation of anger; but it was only momentary, and soon passed away. Though apparently calm and quiet, he was excitable and singularly emotional. An act of injustice towards a personal friend would arouse his indignation, as the contemplation of pain or the tale of distress experienced by others would often move him to tears. A few months before his death, he delivered his last public address as President of the South-Western Branch, giving short accounts of some of the more distinguished physicians and surgeons that had preceded him in Exeter. When he came to speak of those with whom he had been personally associated, and for whom he entertained veneration and esteem, his voice and his manner evinced the susceptibility of his mind.

Mr. Delagarde was well versed in the more solid literature of the day. He often contributed short papers to the medical journals. His writings were essentially practical, and filled with details of cases that had passed under his own observation. The most conspicuous type of these was the address on Surgery which he delivered at Torquay in 1860 before the British Medical Association. He also took great interest in archaeological investigations, and was one of the founders of the Exeter Diocesan Architectural Association. He contributed papers not only to its *Transactions*, but to the *Archeologia*, and to the *Transactions of the Institute of Civil Engineers*; one of his contributions, a *History of the Exeter Canal*, obtained for him the Telford medal.

In the earlier part of his career, he was a member of the old borough corporation. He was Sheriff in 1832, and, in 1834, Mayor—the last under the old charter. After the passing of the Municipal Reform Bill in 1836, he only on rare occasions spoke in public, and then chiefly on matters connected with his profession. In his diction, he was clear, distinct, and elegant; lucid in arrangement, and self-contained; fluent, and impressive.

He was simple in his tastes, and unostentatious; content with the quiet social sphere in which he moved. He was an English gentleman of the good old fashion; punctilious even in his observance of the unwritten laws of honour; high-minded and independent, staunch to his principles, and of sterling integrity.

In person he was about the middle height, somewhat spare, firmly built, and, for his size, of great muscular power. For many years, he

performed his professional journeys on foot or on horseback; but in late years, attacks of lumbago, and then of bronchitis, obliged him to use a carriage. His features were marked, sharp, and somewhat hard—latterly, he had adopted the fashion of a beard.

He continued in the active exercise of his profession to the last, and may be said to have died in harness. An early summons to an old patient on the 17th of September, was the cause of an illness that attacked him in the course of the day whilst at the Hospital. With difficulty he walked home to occupy the bed from which he never again rose. Naturally of a strong constitution, his physical strength only gradually failed. He retained his mental faculties to the last.

In 1826, he married Susan, the second daughter of his old schoolmaster, the Rev. Dr. Lempriere. She died just one year before him. Of five children, two daughters survive him. His eldest son died early. His second son had given an early promise of a bright career; and Mr. Delagarde had ardently hoped that he would succeed him in the estimation of the public as a surgeon. For a few years, he was his father's coadjutor at the Eye Infirmary, but died before him at the age of 35, leaving an only child, a son, to carry on the name.

#### GEORGE BULLEN, F.R.C.S., IPSWICH, Late Surgeon to the East Suffolk Hospital.

WE have to record the death of Mr. Bullen, which took place, at the age of 80, on November 11th. He was born at West Downham, in the Isle of Ely, in 1791, his father being at that time curate of the parish. In 1813, he became a member of the Royal College of Surgeons, and went for a short time as assistant to a medical man at Birmingham. He soon returned to Ipswich, and became assistant to Mr. Stebbing (whose pupil he had formerly been), and at the death of the latter, started in practice in the town. Upon the establishment of the East Suffolk Hospital he was elected one of the surgeons, and held the appointment until about two years ago. He was a very successful operator, and operated for stone more than fifty times, seldom losing a patient. He had a very fine collection of calculi, which are now deposited in the Museum of the Royal College of Surgeons. Mr. Bullen was well read in medical and general literature, and had a good knowledge of the fine arts. He was at one time elected an alderman of the borough, but resigned the office after holding it about six months. He was President of the Public Library, and also a member of the Museum Committee, and of the Dock Commission. Mr. Bullen was twice married, but outlived both his wives. He leaves a family of daughters by his first wife; but his only son, who was a rising medical man in Ipswich, died a few years ago.

## MEDICAL NEWS.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—The following candidates have successfully passed the examinations for the License to practise Medicine, held on November 1st, 14th, and 15th.

Coppinger, Charles Philip  
Crookshank, Harry Maule  
Doyle, Jeremiah

Galgey, Otho  
May, Walter  
Ward, Michael Francis

The following obtained the License to practise Midwifery, at the examination held on November 16th.

Beamish, James Maybury  
Crookshank, Harry Maule  
Doyle, Jeremiah  
Elliott, Christopher

Galgey, Otho  
May, Walter  
Smith, James Edward

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 16th, 1871.

Hoskings, Ethelbert, Woburn Square  
Parkhouse, Henry, Braintree, Essex  
Whittington, Charles Edward, Tuxford, Nottinghamshire

The following gentlemen also on the same day passed their first professional examination.

Lewis, Frederick William, Middlesex Hospital  
Paradise, Thomas Decimus, Guy's Hospital  
Warren, Alfred, Charing Cross Hospital  
Whitaker, James Sealy, Guy's Hospital

As an Assistant in compounding and dispensing medicines.  
Kimber, Benjamin Tindall, Southampton

#### MEDICAL VACANCIES.

**THE following vacancies are announced:—**  
**AMERSHAM UNION.**—Medical Officers and Public Vaccinators for the Chesham Nos. 1 and 2 Districts: £70 per annum, and Vaccination Fees.

**BIRMINGHAM and MIDLAND EYE HOSPITAL**—House-Surgeon: £80 per annum, apartments, board, and attendance.  
**BLVTHING UNION, Suffolk**—Medical Officer for the Wrentham District: £43 per annum, and extra fees.  
**BOSMERE and CLAYDON UNION, Suffolk**—Medical Officer for the Claydon District: £42 per annum, and extra fees.  
**BRADFORD FEVER HOSPITAL**—Two Honorary Medical Officers.  
**BRISTOL GENERAL HOSPITAL**—Surgeon.  
**CARNARVONSHIRE and ANGLESEY INFIRMARY**—House-Surgeon.  
**CHARING CROSS HOSPITAL**—Surgeon-Dentist.  
**CLAREMORRIS UNION, Co. Mayo**—Medical Officer for the Ballyhannis Dispensary District: £100 per annum.  
**CRIEFF, Perthshire**—Certifying Factory Surgeon.  
**DERBYSHIRE LUNATIC ASYLUM, Mickleover**—Superintendent-Physician: £600 per annum, lodgings and rations.  
**DEVON and EXETER HOSPITAL**—Surgeon.  
**EVELINA HOSPITAL FOR SICK CHILDREN**—Medical Registrar.  
**GENERAL HOSPITAL, Birmingham**—House-Governor and Secretary: £200 per annum, board and residence.  
**GRANTHAM UNION, Lincolnshire**—Medical Officer for the Grantham District.  
**GREAT NORTHERN HOSPITAL**—Surgeon.  
**HEXHAM UNION, Northumberland**—Medical Officer for the Western Division of District No. 3.  
**LAMBETH**—Medical Officer of Health: £500 per annum.  
**LEEDS HOSPITAL FOR WOMEN and CHILDREN**—Assistant-Surgeon.  
**LINCOLN COUNTY HOSPITAL**—Dispenser.  
**LIVERPOOL ROYAL INFIRMARY**—Physician.  
**LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE**—Lecturer on Ophthalmology.  
**MADDERLY, Perthshire**—Parochial Medical Officer.  
**MOUNTMELICK UNION, Queen's County**—Medical Officer for the Coolrain Dispensary District: £90 per annum, and Registration and Vaccination Fees.  
**REETH UNION, Yorkshire**—Medical Officer for the Muker District: £22:10 per annum, and extra fees.  
**ROYAL INFIRMARY, Edinburgh**—General Superintendent: £420 per annum, and house rent.  
**ST. MARY ABBOTTS, Kensington**—Medical Officer for part of the Parish of, for six months: at rate of £75 per annum.  
**ST. MARY'S HOSPITAL and DISPENSARY for WOMEN and CHILDREN, Manchester**—Medical Officer: £60 per annum, board and residence.  
**SOUTH STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton**—Physician's Assistant: £100 per ann., with board, washing, and furnished apartments.  
**STOCKPORT INFIRMARY**—Assistant-Surgeon: £60 per annum, board and apartments.  
**SUSSEX COUNTY HOSPITAL, Brighton**—Surgeon; Assistant-Surgeon.  
**TORQUAY, Devon**—Medical Officer of Health: £100 per annum.  
**VICTORIA HOSPITAL FOR SICK CHILDREN, Chelsea**—House-Surgeon.  
**WANDSWORTH and CLAPHAM UNION**—Medical Officer for the Workhouse and Infirmary: £250 per annum, and furnished apartments.  
**WEST OF ENGLAND EYE INFIRMARY, Exeter**—Surgeon.  
**WOODBIDGE UNION, Suffolk**—Medical Officer for District No. 5: £62:10 per annum, and extra fees.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

- \***COOPER, Alfred, Esq.**, appointed Surgeon to the Royal Hospital for Diseases of the Chest, City Road, vice \***F. Mason, Esq.**, resigned.  
 \***ELDER, George, M.B.**, appointed Resident Surgeon to the General Hospital, Nottingham, vice **A. G. Mickley, M.B.**, resigned.  
 \***HAYARD, D., Esq.**, appointed Medical Officer to the Newport district of the Cardigan Union; also Admiralty Surgeon and Agent at Newport, Pembrokeshire.  
 \***LAWRENCE, H. Cripps, Esq.**, appointed Pathologist to the Sophia Nursery for Infants, Fulham.  
**PHILLIPS, Sutherland Rees, M.D.**, appointed Assistant Medical Officer to the Devon County Asylum.  
**ROWAN, John Foster, L.K.Q.C.P.Irel.**, appointed Medical Officer for the Kilkee Dispensary District of the Kilrush Union, Co. Clare.  
**SPENCE, Robert, M.D. Edin.**, appointed Medical Officer and Public Vaccinator for the Parishes of Cavers and Minto, Roxburghshire.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

#### BIRTH.

**WORKMAN**—On November 16th, at Clarendon Terrace, Teignmouth, the wife of \***C. J. Workman, M.D.**, of a son.

#### MARRIAGE.

\***CHALDECOTT, H., Esq.**, Surgeon, to Emma Louisa, widow of the late **S. DANDY, Esq.** of Calcutta, and eldest daughter of the late **Allan Webb, M.D.**, Bengal Medical Service, at Dorking, on November 16th.

#### DEATHS.

**BULLEN, George, Esq.**, Surgeon, at Ipswich, on November 11th.  
**CAMACK, Thomas Armstrong, M.D.**, at Boston, aged 46, on October 27th.  
 \***DELMAGUER, Philip C., Esq.**, Surgeon to the Devon and Exeter Hospital, at Exeter, aged 74, on November 17th.  
**STANFORD, Wm. H. N., A.B., M.B.**, at Shankill, co. Dublin, on November 13th.

**TESTIMONIALS**.—**Dr. Wallace, of Greenock**, has been presented with a silver salver and a sum of between £300 and £400 by a few patients, as a token of regard and acknowledgment, on his going to the Mediterranean for health.—**Mr. Thomas Coe, F.R.C.S.E.**, has been presented with a handsome silver epergne, inscribed as a small token of respect, after thirty years' service, by the officers and brothers of the Loyal St. Edmund Lodge.

### OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**THURSDAY** ... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
**SATURDAY** ... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**.—Medical Society of London, 8 P.M. Mr. Wm. Adams, "A Case of Webbed Fingers treated by Mr. Tamplin's Instrument"; Mr. Alfred Freer (Stourbridge), "Case of Impalement"; Mr. Brudenell Carter, "Ophthalmic Demonstrations."  
**TUESDAY**.—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. Fairlie Clarke, "On Unilateral Atrophy of the Tongue"; Dr. Priestley, "On Inter-menstrual or Intermediate Dysmenorrhœa."

### EXPECTED OPERATIONS AT THE HOSPITALS.

**WEST LONDON HOSPITAL**, Thursday, November 30th, 2 P.M. External Urethrotomy, and Operation for Vesico-vaginal Fistula, by Mr. Teevan; and Operation for Fistula in Ano, by Mr. Cooper.

### NOTICES TO CORRESPONDENTS.

*ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.*

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

For replies to questions concerning Poor-law medical questions, see Poor-law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Maunsell, Dublin.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**DR. SHAPTER (Exeter)** and **DR. LEVY (Berlin)** are thanked for their communications.

**DR. TILT**.—In an early number.

The requests of **Mr. Morris, Mr. Mash, and Dr. Currie Ritchie**, have been attended to.

**VACCINATION GRATUITIES**.—Non's letter shall appear in an early number.

**SIR**.—Will you kindly inform me if I am legally entitled to put on my door-plate "Surgeon" as well as "Dr.," my only qualification being M.D.?  
 November 1871. I am, etc., H. R. H.

**P.S.**—My diploma states that it gives a right to practise in all the departments of medicine.

\*.\* This diploma is only registerable as a medical diploma.

**DR. BRAXTON HICKS, Mr. Gaskoin, Dr. Stanley Haynes**.—In an early number.

#### INSUPERABLE CONSTIPATION.

I OBSERVED a notice a fortnight since in the JOURNAL of a paper to be read at the Hunterian Society, of which we should all have been glad to have some further information. You published lately a very useful series of records of the Treatment of Obstinate Constipation by metropolitan and provincial hospital physicians. Mr. Bryant goes a step further, and discusses "Insuperable Constipation and its Treatment." If it be insuperable, I am a little curious to know how it is to be treated?—A. S. S.

\*.\* By colotomy, we presume.

WE cannot concur with an Associate, that the remedy which he has found successful in the cure of "nocturnal spermatic emission"—gentian and brandy—is a desirable or advisable means of treatment. Bromide of potassium is amongst drugs the most useful; and the general mental and physical hygiene necessary are well described by most standard writers.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

### CAUTION.

It having come to the knowledge of the Publisher that circulars have been distributed calculated to mislead advertisers as to the circulation of this journal, he feels it incumbent on him to state that its circulation far exceeds that of any other medical periodical, and that it has for many years past steadily increased, and is still increasing.

**A YOUNG MEMBER (Liverpool).**—On inquiry, we learn that there will be an examination for the License in Midwifery early in the ensuing month. The advertisements will appear next week giving full particulars.

**ERRATUM: THE CLINICAL SOCIETY.**—Dr. Playfair writes to say that, in the discussion on Thoracentesis, he, in speaking of empyema, said that, when the pleura contained pus, the chances of absorption were reduced to a minimum, and that, therefore, continuous drainage was to be preferred to simple thoracentesis; and then proceeded to describe a method of effecting this without admitting air into the pleural cavity, which he had found of great service. The report as published in last week's JOURNAL was incorrect in representing Dr. Playfair's remarks.

**M.** does not state his age, nor the purpose for which he requires books on the subjects named. There exist, of course, good elementary handbooks and full treatises on all the subjects; but, on the scanty data which he gives, our advice might be in its results more costly than useful to him.

### ROUGH EXAMINATION OF WATER.

**SIR,**—In reply to the inquiry (in last Saturday's JOURNAL) of Mr. Charles M. Thompson, for an inexpensive mode of analysing water, I can confidently recommend the following, presuming that it is for *organic* impurities that he wishes to test. I owe the knowledge of this simple but valuable plan to Dr. Attfield, Professor of Chemistry to the Pharmaceutical Society.

Brighton, November 20th, 1871.

I am, etc.,

G. F. HODGSON.

\*. Half-fill a good-sized decanter (previously quite clean) with the suspected water, fill its mouth, shake well, and then apply the nose. If nothing unpleasant is detected, close the bottle tightly, and set it aside in a warm place—98 or 100 deg.—for two or three days, and then repeat the shaking, etc., as at first. If this time no foul odour is detected, the water is not of very bad quality. Smaller amounts of organic matter, and the exact character of other constituents of water, can only be determined by chemical analysis.

**COLLECTION OF SUBSCRIPTIONS.**—Notwithstanding Dr. Colville Brown's belief that he is not a member of the local Branch, it appears from the statements of the General and the Local Secretaries that he was so elected, and appears in the printed lists of the Branch. As a member in arrear after October, he ought nevertheless to have fallen under the supervision of the former officer for the collection of the subscription which he has been desirous to pay.

### ARRANGEMENTS OF ANNUAL MEETINGS OF THE ASSOCIATION.

**SIR,**—I am a member of three associations holding annual gatherings for mutual instruction and encouragement, as well as for promoting knowledge we value in the various localities we visit. These three associations for the promotion of general, of medical, and of social science, all pursue much the same plan, and all commit, and persist in committing, the same mistake—they gather together from every part of the country, and often from other countries, men eminent for their abilities, from whom all cultivating the same branch of knowledge are most anxious to learn, but are prevented from learning because the available time is nearly all occupied by listening to papers read, many of which would be far better understood if quietly read at home. It is very true that some of these papers form the basis of useful and interesting discussions; but it is scarcely possible to discuss any one subject satisfactorily, because we always will try to discuss too many subjects at once. It is also true that it is impossible to foretell which of the papers will elicit the most interesting discussion; and those who arrange the meetings are naturally unwilling to omit any promising paper, lest it should be one of those which will prove the introduction for an interesting debate. I submit, however, that it would be possible to get nearly, if not quite, all the benefits of the good papers, without being embarrassed by a multitude of those of little importance, and without occupying the time of many by reading what few may care to hear. All that would be necessary would be, first, to accept no papers that are not sent in for perusal and selection a month or two before the meeting; secondly, to accept none that are not judged to be worth printing: what is not worth printing, is not worth occupying the time of men whose time is valuable. Ten pounds an hour is a very low estimate of the value of the time of twenty of our members; to save that time at a cost of five pounds for printing, would be good economy. Lastly, the papers accepted and printed should be sent to each member to read before the meeting, at which the title only, or at most a short abstract of the paper, should be read, so that nearly all the time now occupied in reading would be available for discussion, the only sensible object for gathering as many as possible of the most eminent cultivators of the same science together, which object is now to a great extent defeated; while our members are mortified at knowing that those who could give them most valuable and interesting information, are compelled to limit themselves to a few hurried observations, and often to be altogether silent.

Along with much good, no little mischief is done by this system of imperfect discussion. Crude and mistaken opinions and injurious fallacies are put forth under the *apparent* sanction of an important association, without being corrected or exposed, which would, under a better system, have a very short life of it.

Men of business, who seldom forget that time is money, have long since adopted the plan here suggested; they attach too just a value upon their time to allow it to be wasted in listening to long reports read slowly at a meeting, which they can quickly examine at their leisure. At most meetings of town councils, railway and other companies, all long reports are printed and circulated beforehand, and at the meeting taken as read, attention being specially directed to the portions needing explanation. By this plan, not only is business done more quickly, but also far better, by attention being concentrated on the subjects needing it. The time is, I trust, not far distant when men of science will show that they also know the value of time.

I am, etc.,

P. H. HOLLAND.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

### ANÆSTHETICS AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

**SIR,**—Perhaps you would kindly excuse my making a little more clear what I observed, perhaps imperfectly, in the late debate on ether in the Royal Medical and Chirurgical Society. I should not trouble the reader, but that curiously inexact reports of this important discussion have appeared elsewhere, that only mislead and helplessly obscure the subject. The ether of the shops is miscible with water in many instances; and so is very unreliable and tedious. Thirty-six deaths during inhalation of ether have been recorded by Sabarth; so that it is not entirely free from danger as alleged. The paper of the evening called in question Mr. Lister's views as lately explained in the JOURNAL, holding rather the pulse to be the chief test or guide as to the safety of chloroform during its administration, and doubting the views generally of the Scotch school. This, of course, is a question of simple clinical observation; and though I doubt Mr. Lister's necessity for fear when stertor occurs, I cannot help thinking he is right as to the pulse, and said so. The necessity for complex inhalers, and mystery as to chloroform administration, are but corollaries on this supposed fact of cardiac syncope and the pulse being a test of danger. Again, as to the methylene chloride, I said I had observed its usefulness in short operations like cataract (it is specially valuable in iridectomy and glaucoma, where it is desirable that the vitreous humour should not be disturbed by vomiting or muscular plunging, such as follows chloroform when not given with skill); it is very uncertain, however, in composition, I also remarked, and has proved far more deadly than chloroform or the nitrous oxide in actual practice, though theory supposed it would be less deadly; on this account, it does not strike one as the best anæsthetic in midwifery or ovariotomy cases, where chloroform is better understood by patients, and acts so admirably. On the whole, it is scarcely judicious to say ether is entirely free from danger, and should supersede chloroform; that only with special apparatus and watching the pulse is chloroform safe; or that the methylene is safer than chloroform or nitrous oxide. Ether relaxes muscular tissue and is useful in reduction of dislocations; this was not mentioned during the evening. This property recommended it (by theory) in midwifery at first; but in America it was observed that it failed, as the perineum is chiefly made of fibrous rather than muscular tissue, and three or four ounces of chloroform would do as much in a case as almost a pint of this ether of the shops.

I would only here add that, in these impressions as to iridectomy, I am fully borne out by such an excellent observer as Dr. Bader at Guy's Hospital, that in ovariotomy, where Mr. Spencer Wells recommends the methylene so strongly, almost any fluid anæsthetic will answer. I have watched the pulse and breathing in over a hundred ovariotomies; as to ether, too, I remember distinctly Mr. Hayward of America helping in its administration at one or two hospitals, and usually carrying about a quart of it as an ordinary allowance for each capital operation; and it failed utterly at one hospital, as explained at the time by the hospital ether being miscible with water.

I am, etc.,

CHARLES KIDD, M.D.

Sackville Street, November 12th, 1871.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Freeman's Journal and Daily Commercial Advertiser, Nov. 15th; The Shrewsbury Chronicle, Nov. 17th; The Brighton Herald, Nov. 18th; The Retford, Worksop, Isle of Axholme, and Gainsborough News, Nov. 18th; The Dublin Evening Express, Nov. 17th; The Bedfordshire Mercury, Nov. 18th; The Midland Counties Express, Nov. 18th; The Sheffield Daily Telegraph, Nov. 22nd; The Irish Time, Nov. 18th; The Ipswich Chronicle, Nov. 8th; etc.

### COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. Forbes Winslow, London; Dr. Hughes Bennett, Edinburgh; Mr. Berkeley Hill, London; Mr. Husband, York; Dr. Cotton, London; Dr. Tilt, London; Dr. B. W. Foster, Birmingham; Dr. H. Cripps Lawrence, London; Mr. Robert Goodbody, Mountmellick; Mr. Rowland H. Coombs, Bedford; Dr. De Zouche, Berlin; Mr. Casey, Carlow; Dr. W. Ogle, Derby; Dr. Connor, Detroit, U.S.A.; Mr. R. Ellis, London; Mr. Holland, London; Dr. Bradbury, Cambridge; Our Dublin Correspondent; Dr. J. Braxton Hicks, London; The Secretary of the Obstetrical Society; Mr. Creighton, Berlin; Dr. Walters, Reigate; Mr. Charles Woodcock, Bradford; Dr. J. Warburton Begbie, Edinburgh; Mr. H. H. Read, Oxford; Mr. J. Mash, Northampton; Mr. Manson, Howden; Dr. Sheen, Cardiff; Mr. C. H. Carter, Pewsey; Mr. Sydney Jones, London; Mr. C. L. Goehring, London; Dr. Kirby, London; Dr. Madge, London; Dr. Leared, London; Mr. Nicholson, Hull; Mr. de Méric, London; Dr. Carpenter, Croydon; The Secretary of the London Institution; Dr. John Harley, London; Dr. Shapter, Exeter; An Associate; Mr. H. Wathen, Fishguard; Dr. Julius Levy, Berlin; Dr. Campbell Black, Glasgow; Mr. Leeds, Sheffield; Dr. Morton, Glasgow; Mr. Hall, Tunbridge Wells; Mr. Bellamy, London; Dr. Smith, Aberdeen; Mr. Hinton, Warminster; Dr. Rees Phillips, Exminster; Mr. J. L. Morley, London; The Secretary of the Pathological Society; Mr. Moore, Moreton-in-the-Marsh; Mrs. Brookes, Stockport; Dr. Playfair, London; Mr. Gaskoin, London; Mr. B. Wilson, London; Mr. Latimer, Plymouth; Messrs. Ingram and Co., London; The Secretary of the Clinical Society; Dr. Fraser, Colchester; Dr. Sedgwick, London; Mr. Reginald Harrison, Liverpool; Mr. Hodgson, Brighton; Dr. J. Rose Cormack, Paris; Messrs. Black, Edinburgh; M.R.C.S.; Dr. George Johnson, London; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Mr. R. S. Harvey, Harrogate; Mr. E. Chapman, London; Mr. W. Hopcraft, London; Dr. McAdam, Edinburgh; The Secretary of the Royal Medical and Chirurgical Society; Mr. J. E. Cornish, Manchester; Mr. W. Jones, Ty-Newydd; Mr. R. Freeman, London; M.D.; Our Manchester Correspondent; A Public Vaccinator; Dr. Woodward, Leicester; Our Vienna Correspondent; Nemo; Dr. Woodman, London; Captain Burton, London; Mr. S. M. Bradley, Manchester; Mr. G. Elder, Nottingham; Studens; Mr. Benson Baker, London; P. L. O.; Dr. Maunsell, Dublin; Dr. Henry Bennet, Mentone; Dr. Todhunter, Dublin; Dr. Rendle, Clapham; Mr. Jessop, Leeds; Mr. Brown, Littlebourne; etc.

## IMPORTANT NOTICE TO THE PROFESSION.

**DR. RIDGE'S FOOD** is rich in solids and earthy salts. The phosphates of potash and magnesia exist naturally, and are not introduced by any chemical process. As nature has produced them, so are they conserved and kept free. The nitrogenous substances are varied, consisting chiefly of soluble albumen and gluten. In the preparation of this Food, the outer covering of the grain used is carefully removed, for it is well known that the smut (which is a species of puccinia) lives upon the surface of wheat, and is apt to cause diarrhoea in children. The Food is so thoroughly desiccated that neither the *Acarus Farinae* nor the *Vibroni* can live in it. This renders this article of diet superior to all others, for it not only builds up healthy tissue, but prevents the introduction of any vegetable or animal parasite, which is often the cause of the incessant diarrhoea of children. Medical men, by sending their card to the Manufactory at Bermondsey, can receive a tin of food for trial, free of charge.

Sold in Packets and Canisters by respectable Chemists and Grocers.

**THE VICHY WATERS COMPANY**, 27, Margaret Street, Cavendish Square,  
AND 61, QUADRANT, REGENT STREET, LONDON, W.

General Depôts for the Natural Mineral Waters belonging to the French Government. Importers of all other Mineral Waters. Liberal discount to the Profession. Price Lists free.

**NATURAL MINERAL WATERS OF VALS, VICHY, CARLSBAD, SELTZER, KISSENGEN, HOMBURGH, PULLNA, FRIEDRICSHALL**, etc., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co., at the Royal German Spa, Brighton, and the **NATURAL BROMO-IODINE WATER** of **WOODHALL SPA, LINCOLNSHIRE**.

Agents—**W. BEST and SONS**, 22, Henrietta Street, Cavendish Square, London, W.

**NATURAL MINERAL WATERS OF VICHY, SELTZER, PULLNA, KISSINGEN, CARLSBAD, MARIENBAD, SCHWALBACH, FRIEDRICHSHALL, SPA, EMS, KREUZNACH**, etc., direct from the Springs.

A Pamphlet on Natural Mineral Waters forwarded on application.—Depôt for the **NATURAL BROMO-IODINE WATER** of **WOODHALL SPA**.

**INGRAM and CO.** (Importers), 35, BUCKLESBURY, LONDON, E.C.

## PEPSINA PORCI.

Messrs. **BULLOCK & REYNOLDS**

Beg to direct the attention of the Profession to the experiments upon Medicinal Pepsin by Professor Tuson, recorded in the *Lancet*, August 13th, 1870, which incontestably prove the very great superiority of their preparation in point of digestive power over every other Pepsin, British or Foreign. Dose—two to four grains.

Messrs. **BULLOCK and REYNOLDS** will be happy to forward, post free, a Reprint of Professor Tuson's Paper on application.

3, HANOVER STREET, HANOVER SQUARE, W.

SILVER MEDAL AWARDED 1867.—JUROR 1862.

## MORSON'S PREPARATIONS OF PEPSINE. MEDICINAL PEPSINE

(Poudre Nutritive, or "Pepsine Acide Amylacée" of the French Codex).

Contains the active digestive principle of the gastric juice, purified and rendered permanent and palatable. Dose—15 to 20 grains.

### PEPSINA PORCI,

A concentrated and NEUTRAL preparation of Pepsine, free from any disagreeable taste or smell. Dose 5 to 10 grains.

These preparations of Pepsine are carefully examined and tested by a Professional Chemist, and certified to answer to the tests indicated. Every bottle containing the preparations named, and bearing the Trade Mark of T. MORSON and SON, is sold with a guarantee to that effect.

**PEPSINE WINE.**

**PEPSINE LOZENGES.**

**PEPSINE GLOBULES.**

Are convenient forms for the administration of Pepsine.

### SACCHARATED WHEAT PHOSPHATES,

A Dietetic Preparation, supplying an important deficiency in the ordinary Food of Invalids and Children.

Manufactured by **T. MORSON & SON, Pharmaceutical Chemists**,

31, 33, and 124, SOUTHAMPTON ROW, LONDON, W.C.

## "MILLER'S" IMPROVED BELT,

TO LACE, BUCKLE, OR PULL ON.

**W. MILLER,**

ANATOMICAL MECHANICIAN,

29, LEICESTER SQUARE, LONDON, W.C.

## Van Houten's Cocoa.

The only guaranteed Pure Soluble Cocoa, better and cheaper than any other Cocoa, Cocoa Extract, or any Chocolate.

*The British Medical Journal*, March 27th, 1869, says:—"Van Houten's Extract is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich in alkaloid," &c., &c. See also *The Lancet*, etc.

Sold in round Tins at 3s. 6d., 2s., and 1s. Sample Tins, sufficient for a family, free of charge, through your Grocer or Chemist.

# CLINICAL LECTURES ON OPHTHALMOLOGY.

*Delivered at St. Thomas's Hospital, London.*

By R. LIEBREICH,  
Ophthalmic Surgeon and Lecturer to the Hospital.

## LECTURE V.

### ON A NEW METHOD OF EXTRACTION OF CATARACT.

GENTLEMEN,—Until now we could perform but small operations at our Thursday meetings. The Ophthalmic Ward having been opened last week, we shall be able to receive patients for operations of greater importance. We shall begin with cases of iridectomy and cataract; and, as for this latter, I shall have to explain to you my new method of extraction, the more detailed description of which will appear in our next *Hospital Reports*.

The frequent occurrence of total suppuration after flap-extraction induced the celebrated operators of Moorfields Hospital to return to, and to improve, the linear extraction, which at that time had been almost abandoned. Graefe, struck with the results which Messrs. Bowman and Crichtett had obtained, submitted the question to further studies, and so formed the method which is now generally adopted in England as well as on the Continent.

There are numerous statistics which prove that in Graefe's method there is a much smaller percentage of total suppuration than in flap-extraction; also that, even in cases of very bad general constitution, weak and marastic individuals with thin and flabby cornea, the prognosis is not so unfavourable as in flap-extraction; and that the precautions we have to take after the operation, and the restrictions we have to impose upon the patient, are not so great.

On account of these advantages of Graefe's method, it was natural that the flap-extraction was soon abandoned. To me, however, it appeared that the mechanism of Graefe's operation was still too complicated and too violent; that prolapse of the vitreous body and hæmorrhage into the anterior chamber were too frequent during the operation, iritis and strangulation of the iris in the corners of the wound too frequent after it; and that the most favourable results, compared with the most favourable results in flap-extraction, were not perfect enough.

If these inconveniences be carefully inquired into, it is found that they can all be brought back to one and the same principal cause—namely, the peripheric position of the incision. This peripheric position explains why—

1. It is impossible to remove the lens without iridectomy.
2. The excision of the iris is to be large and extensive, else it causes too great an inclination to prolapse of the iris.
3. It is necessary to perform the operation above, so as to cover a part of this large pupil by the upper eyelid. The removal of the lens upwards is by far more difficult, on account of the tendency of the eye to escape upwards; and, consequently,
4. During the whole operation, the eye has to be kept open by the speculum, and to be drawn downwards by the forceps. This is not only painful and injurious to the eye itself, but causes—
5. Not unfrequently, prolapse of the vitreous body, to which a peripheral incision itself already tends. Prolapse of the vitreous body and hæmorrhage into the anterior chamber are the chief impediments to a careful removal of all the *débris* of the cortex, and cause—
6. Those grave forms of iritis which are sustained by the permanent irritation caused by the tumefied remainders of the lens behind the iris.

Of those disadvantages I was perfectly aware after I had followed for a short time Graefe's original plan; and I proposed, therefore, in 1867, in an article on Cataract which I wrote for the *Nouveau Dictionnaire de Médecine et de Chirurgie* (Paris, Baillière), some modifications. They are, however, but the first step I made; and in the last four years

I have come, by a large series of systematic experiments, to a method which I now, after more than three hundred operations performed in this manner, consider definitely settled.

The incision of the cornea is to be made with the smallest possible Graefe's knife, in the following manner.

Puncture and contrapuncture are made in the sclerotic about one millimetre beyond the cornea, the whole remaining incision passing with a very slight curve through the cornea, so that the centre of it is about one millimetre and a half distant from the margin of the cornea. This

incision can be made upwards or downwards, with or without iridectomy, and the lens can be removed through it with or without the capsule.

If, as I now practise, the extraction is made downwards without iridectomy, the whole operation is reduced to the greatest simplicity, and does not require narcosis, assistance, elevator, or fixation; and only two instruments—namely, Graefe's knife, and one cystotome, with Daviel's spoon.

What are the advantages of this method of operating?

1. It is undoubtedly of all methods the simplest and the least painful.

2. It is unconditionally the easiest to perform, and requires the least practice. It may, therefore, be performed by those operators who from time to time only have an opportunity of doing so; and those patients benefit by it who are unable to reach a central point in order to place themselves in more practised hands. On account of the greater facility of operating, the last pretext for reclamation of cataract is removed, which, though almost universally and justly condemned, is still here and there performed.

3. It is preferable to the flap-extraction, on account of the safer and constantly regular incision. The flap-incision scarcely ever acquires the regularity which may theoretically be demanded—even if made by the most practised operator, with the best assistance, the most enduring patient, or under chloroform—by the use of elevator and fixation instruments. Now its height or breadth is not what it is intended to be; now its position is incorrect, or the wound is irregular—indeed, part of it is due to the difficult form of the incision; but by far the greater part, according to my conviction, is due to the mechanism by which the cuneiform cataract-knife is to make the incision. A small Graefe's knife would make a flap safer and more regular than the various other cataract-knives. The incision which I designed can easily be made, in giving it in every case exactly the desired form and position—even if the patient is very restless—without assistance, without elevator or fixation. It mainly depends on the facility with which the place of the contrapuncture can be chosen, the knife drawn back and made to pierce at another point if a mistake is made in the selection of the place for contrapuncture, and in the freedom with which, in terminating the incision, the inclination of the knife can be changed if necessary.

A little practice will enable every operator to avoid these corrections, and to make the contrapuncture, as well as the whole incision, correctly to his original plan, without subsequent alterations.

4. Against Graefe's method it has the advantage of a more favourable position of the field for the operation, and avoids through it all the inconveniences to which I have referred, as arising out of the peripheral position of the wound.

5. In regard to the mode of healing, it favourably contrasts, like Graefe's method, with the flap-extraction, on account of the diminished influences which age, constitution, general state of health, season, and other causes exert; also on account of the less damage made upon the patient to remain quiet after the operation; and, above all, on account of the lesser tendency to suppuration of the cornea.

6. The advantages of my method over that of Graefe are shown by the ultimate results obtained; by not showing a greater percentage of total suppuration than in Graefe's method, my best results are in regard to optical and (if I may use the term) anatomical perfection, identical with the best results obtained in flap-extraction.

# RETROSPECTIVE ADDRESS

OF THE

## PATHOLOGICAL SOCIETY OF READING.

Read September 27th, 1871.\*

By WILLIAM ROYDS, L.R.C.P.Lond.

**III. OBSTETRIC CASES.**—With the usual candour for which the Society is so deeply indebted to Mr. Walford, he brought forward some of his unsuccessful cases.

*Intrauterine Cancer: Haemorrhage.*—The first was a patient, in her thirty-fourth year, whom he had attended in several confinements, and for whom he had more than once to remove the placenta by the hand.

In August, 1870, he again saw her, with threatening of miscarriage at the fourth month. On account of a shivering fit and quickened pulse, he thought it right to empty the uterus, which he did on the 1st of September. On the 7th, hæmorrhage took place, requiring the introduction of a plug. This was removed on the 8th, and she seemed on the road to recovery; but the same night the sponge, which he used as a plug, had to be replaced. Hæmorrhage, nevertheless, continued to some extent, and the patient sank and died on the 9th. The condition, as revealed by a *post mortem* examination, seemed to Mr. Walford to justify his returning the cause of death as "cancer of the mucous membrane of the uterus and hæmorrhage."

*Abortion.*—Another case of Mr. Walford's was an abortion at six weeks in a woman aged 41, the mother of eight children, who had been accustomed to nurse her children two years. The ovum, with its membranes entire, escaped unexpectedly. An examination of the specimen showed small masses of effused blood in the placenta, constituting apoplexy of that organ, which Mr. Walford concluded to have been the cause of the death of the ovum.

Mr. Walford makes the following remarks in connection with this case. "From the nature of the case I regard it as the effect of weakness; and the history of the patient confirms this inference. She had been accustomed to nurse her children two years—for an obvious purpose—and some may think she did so successfully; certain it is that she did so more successfully than many. From some amount of observation, I am of opinion that weakness is the cause of over-fecundability. Professional observation testifies to the fertility of certain constitutions. A writer in the *Edinburgh Medical Journal* establishes the proposition that twins are a consequence of debility, and that among the imbecile they are of frequent occurrence." From this Mr. Walford was led into an eloquent lamentation over the numbers of increasing families physically below par, the offspring of weakly mothers, which he considered materially diminished the average duration of life in the nation at large, and contributed considerably to the high rate of mortality, especially amongst the children of the lower classes. As a hopeful remedy, he suggested the observance of what he had seen stated as a law of nature—that conception does not take place more than fourteen days after the commencement of menstruation; and with this law of being he thought it became us as patriots to indoctrinate our countrymen.

*Rupture of Uterus.*—Mr. Walford showed a specimen of ruptured uterus. Mrs. —, aged 37, was in labour with her ninth child. Labour had commenced about 7 A.M. He found her at 1 P.M. on the bed moaning more than usual. The os was of the size of a florin, hard and unyielding. The placenta was not within reach. He left her, and soon after he did so, she began to soil the napkins with blood. At 7 P.M. he found the os much in the same state, the patient moaning constantly, the pulse feeble, and the discharge of blood going on constantly. He ruptured the membranes, and saw her again at 8.45 P.M. Her general condition was unchanged. The drain of blood went on, the os had dilated, and it was a question with him whether it was not his duty to turn and deliver. He never once perceived her to have a good uterine pain. On passing his fingers around and within the os, a gush of blood came past them. His conviction was, that the hæmorrhage was "accidental" in its origin, and that in the failure of the rupture of the membranes to arrest it, and in the absence of uterine pains in connection with the feeble state of the circulation and the distress of system as manifested by the moaning, it was his duty to turn and deliver. Accordingly, he did so without difficulty. The child was dead, and had been so some time. Some stimulant with ergol was given, and he proceeded to remove the placenta, which was accomplished na-

turally. He then thought it right to make sure that there were not any clots in the uterus to hinder its effectual contraction, and, on removing one large one and some smaller ones, he found his hand in the middle of a laceration, through which he could reach the intestines and omentum. A few minutes after ten, the patient expired. The uterus was found to be fatty, and presented a rupture some inches in length, with the appearance of several smaller lacerations of its tissue. Mr. Walford advanced the theory that the rupture of the diseased uterus had resulted from its own contractions, and that the hæmorrhage which had occurred was an evidence of that catastrophe. The opinion, however, which found most favour with the Society, and was ultimately accepted by Mr. Walford, was, that the rupture had occurred during the operation of turning, which had been rightly resorted to for the purpose of emptying the uterus of what proved to be a dead child; the hæmorrhage being looked upon as an indication of the presence of a dead foetus.

*Membranous Obstruction of the Vagina.*—Dr. Reid read notes of a case of a woman in her first labour in whom he found the vagina obstructed just within the vulva by a tough fibrous membrane, which he believed to be the unruptured hymen. It had a central aperture through which he was able to pass a female catheter. He incised the membrane, and it proved no obstacle to a natural delivery. After two days its outline was scarcely observable.

*Treatment of Puerperal Convulsions.*—The vexed question of the treatment of puerperal convulsions, with or without bleeding, was raised by Mr. Davis, who communicated a case which had occurred in his practice. Some weeks previously to her confinement, his patient, a woman aged 28, had suffered from oedema of the legs, and the urine had been observed to be thicker and less copious than usual. She was, however, relieved by aperients and mild diuretics. On March 1st, Mr. Davis was summoned to attend immediately, as the patient was said to be in fits. He found her comatose. The pupils were dilated; the pulse small, weak and frequent; the face puffy; the upper and lower extremities anasarctous. The os uteri was just commencing to dilate, and appeared dilatable. The urine was highly albuminous. She had a very severe recurrence of convulsions whilst Mr. Davis was in attendance. He at once proceeded to administer chloroform, and, his assistant keeping the patient completely under its influence, he gradually dilated the os, turned and delivered of a dead child. She had but one slight return of convulsions after delivery, although she remained comatose for many hours. The coma gradually disappeared, however, and she recovered; the urine, highly albuminous at first, returning by degrees to its natural state.

Much discussion followed the reading of this case. Chloroform and bleeding were looked upon as the two remedies, generally speaking, between which a choice was to be made. Bleeding was especially advised by one member in cases in which, from the evidence of the breath, free ammonia was judged to be present in the blood. In that case it was supposed that, by thus diminishing the amount of the poison in the system, the patient's chance of recovery was improved. Other advantages of bleeding were believed to be, its action in diminishing congestion, and so relieving the kidneys, and averting the tendency to apoplexy which sometimes occurred in the fit; and its power of facilitating and hastening labour, which was an important indication. Chloroform was believed, although otherwise a most useful palliative, to be contraindicated in those cases in which there were much ammonia in the blood; but, inasmuch as the means of discovering this fact, simple as it is said to be, may not always be in readiness, it seems desirable that some other indication should be looked for to discriminate between the cases in which chloroform may, and those in which it may not, properly be used.

*Removal of the Uterus.*—Mr. Maurice presented an uterus, considerably enlarged, which he had removed entire from a woman aged 43. She was the mother of six children, and stated that, from the time of her first confinement, which was a tedious one, twelve years ago, the womb had occasionally come down. About a month or so after she had recovered from her last labour, she began to feel uneasy. She had no pain at first, but a burning sensation across the lower part of the abdomen. This was followed by a pain in the back. The womb was at times prolapsed, but was readily returned, and gave so little inconvenience that she never sought any advice. She continued to menstruate regularly up to January last, when she had excessive hæmorrhage, which never entirely left her. In March, she was taken with complete retention of urine for three days, and excessive loss of blood. At this time, she found that the womb was becoming gradually more prolapsed, and did not go back at all. In April it was protruding considerably beyond the vulva; and in the middle of June, while she was straining at stool, the whole uterus suddenly protruded, and she lost a considerable quantity of dark blood. The patient was admitted into the hospital on June

\* Concluded from page 604 of last number.

27th. She was in a miserable condition, extremely emaciated and blanched. The uterus had apparently been first retroverted, and then had become completely prolapsed. The fundus was lowermost, and the os was reached by passing the finger between the vulva, which could not have been had the case been one of inversion, as was at one time supposed. Any effort to return the mass being evidently useless, and the utility of the proceeding, if successful, more than doubtful, a ligature was passed round it and gradually tightened. Two days afterwards, the ligature having broken on being tightened, the chain-*écraseur* was applied in the same groove, and the organ entirely separated, without loss of blood or much apparent suffering to the patient. Her recovery was uninterrupted, and she was discharged from the hospital *minus* her womb, but otherwise in much better plight than when she entered it. An examination of the specimen did not show any sign of the presence of the ovaries; and it was a matter of some surmise what had become of them.

IV. MISCELLANEOUS CASES.—*Recovery after Swallowing a Large Dose of Chloroform.*—This case, related by Mr. George May, is interesting on account of its comparative rarity and the improvement which followed the treatment. The patient was an adult male, and the quantity of chloroform swallowed about two drachms. Almost immediately he made himself vomit by passing his finger into his throat; nevertheless, within about ten minutes, he became unconscious. Mr. May saw him in about half an hour. He was then perfectly insensible, breathing stertorously; the face was livid; the pupils widely dilated, and not contracting on exposure to light; the pulse was full and slowly rising until it reached 120 per minute. The stomach-pump was at once used. An hour after he had swallowed the chloroform, the pulse rapidly fell to 70, and became almost imperceptible; the pupils at the same time contracting. The respirations were 20 in the minute, and at times almost ceased. The countenance was pallid. Half an ounce of sal volatile, with two ounces of water, was injected into the rectum. Decided improvement followed; the pulse at once improved; sensation returned; in two hours after swallowing the chloroform, the patient gave signs of reflex sensibility; and in three hours he had recovered consciousness.

*Vaccination.*—Towards the end of the session, the subject of vaccination was brought before the Society by Dr. Phillips. He laid stress upon the operation being simply the substitution of a mild disease, modified by its transmission through the system of the cow, for a more virulent form of the same affection, and to that attributed its power as a prophylactic. At the same time, he duly cautioned us against any further modification of the disease, such as might result from its transmission through any but the most perfectly healthy human system. He made some reference to revaccination, which he thought need be but once performed after the age of puberty, and that if a person be found insusceptible, we may safely assume that he is so to the influence of small-pox. He quoted the evidence afforded by observations at the Small-pox Hospital, the failure of which, to have weight with any intelligent mind, seems almost incredible. In the operation itself Dr. Phillips strongly recommended, where practicable, the use of liquid lymph, preferring tubes to points, and thought that the best method of performing the operation was by first moistening the part with the vaccine matter and then making punctures or scratches through it. He referred to the subject of vaccino-syphilis, which cases recently investigated had shown to be no myth; and, whilst contending that it was no argument against vaccination, he held that it was a strong argument in favour of extreme care in the method of performing the operation, and especially in procuring lymph unmixed with any other matter from the vaccinifer that might by possibility communicate the syphilitic virus.

In continuation of the subject, Mr. Crisp read an elaborate paper, embodying the results of very careful and complete observations on upwards of three hundred cases of revaccination. Two had been inoculated; and of these one, a lady, aged 40, took perfectly on being vaccinated, and in the other three fair vesicles were found. In three who had had small-pox, no good results followed vaccination. With regard to the method of vaccination and its effect upon results, he stated that arm-to-arm vaccination was done in 195 cases; capillary tubes were used in 85; and points in 25. The results of arm-to-arm vaccination were hardly appreciably better than those done with tubes. Points did not produce quite so good results; but the difference was very trivial. This he attributed mainly to using four or more well and recently charged points in each case. Fifty-one of his cases were revaccinated from the arms of children who had been, or who were stated to have been, vaccinated previously; although, in none of them was there evidence of the first operation having been perfectly successful, and the vesicles of the second operation were perfect. The resulting

effects from using this lymph was in every way as satisfactory as those arising from the use of any other lymph. Mr. Crisp did not, however, give us any evidence of the protecting power of vaccination thus performed; and although the observations on this point are necessarily few, as far as they do go, they have not been such as to encourage vaccination with matter taken from revaccinated persons. Mr. Crisp's cases afford interesting evidence of the relative value of vaccination, well and ill performed, in conferring protection against a second attack of the vaccine disease, and presumably of small-pox. Dividing his cases into four classes, ranging from those in which three or more perfect marks existed to those in which there were no detectible marks, he found a steady decrease in the good results from Class 1 to Class 4. He further noticed that, although the females were found to have on an average half a good cicatrix more than the males, the resulting good effects of revaccination were as nearly as possible exactly the same in both sexes, from which he drew the deduction that the softer sex is of the two the more amenable to vaccine influence.

By a recent change in our arrangements (a change which I regret that the attendance at this meeting does not more fully justify) my retrospective address becomes one of inauguration of the coming session. I trust it may be not less successful than the one on whose work it has been my lot to dwell.

It is usual on these occasions to say something of the advantages of societies like ours. Small need, however, that I should enlarge upon such a topic to my seniors, who have many of them long had personal experience of its benefits, and who still show by their constant attendance at its meetings that their interest in the Society and its work does not flag.

As a means for the spread and cultivation of medical knowledge amongst us, the Society is valuable, and scarcely less valuable is it in its capacity of bringing us together to enjoy friendly intercourse and to cultivate that kindly feeling for which the profession in Reading has the fortune to enjoy a good name, and specially to give scope for the display of friendliness by the senior to the younger members, for which, as one of the latter, I owe a debt of gratitude that I am glad of the opportunity of acknowledging.

Here we may all of us bring our professional joys, and double or more than double them by sharing; and here we may divide and minimise the sorrows of our unsuccessful cases, by sharing them too with those well used to sympathise.

Let us still continue to seek, here and elsewhere, that strength which union may give to fight the battle of our lives against disease and death, and each endeavour to add the result of his experience, be it much or little, to the common armoury from which all may draw as need requires, remembering, as our observations and opinions are here sifted and shaken, that "Truth's like a torch, the more it's shaken it shines."

## THERAPEUTIC MEMORANDA.

### TREATMENT OF CANCRUM ORIS.

I OBSERVE an abstract of a lecture on a fatal case of cancrum oris in a child two years and seven months old, by Dr. W. O. Priestley, at page 577 of the JOURNAL for November 18th. I do not pretend to say that any kind of treatment or application whatever could have saved the child's life, she being in so very weak and emaciated a state as she was when Dr. Priestley first saw her; but it is with regard to the local treatment and remedies used in this case that I beg leave, with all due respect, to object—viz., that the solution of chlorate of potash and borax was not sufficient to check or stay the severe nature of the gangrenous ulcer in the child, although no doubt a very useful application in more simple cases. Of all the local remedies or applications that I have ever resorted to in such cases, I have never found any application so useful or so effectual as hydrochloric acid. Neither nitric acid, nitrate of silver, nor chlorate of potash, nor any other remedy that I ever tried or used, except hydrochloric acid, did I ever find to be of the least use to check cancrum oris. I have almost never found hydrochloric acid to fail to check the progress of this dreadful disease at once, and bring on a most rapid and healthy action in the part. Nor does it cause so much pain or suffering to the little patient as one would suppose, seeing that the gangrenous spot is almost entirely without feeling at this time. This acid is easily applied to the ulcer by means of a feather or a small camel-hair brush. I have cured many cases of cancrum oris by this means.

NEIL MCGREEVY, L.R.C.P. Edin.

Union Hospital, Drogheda, Ireland, November 23rd, 1871.

## ON THE TREATMENT OF FIBROID TUMOURS OF THE UTERUS.\*

By ALFRED MEADOWS, M.D.,

Physician-Accoucheur to and Lecturer on Midwifery and the Diseases of Women and Children at St. Mary's Hospital; Physician to the Hospital for Women; Vice-President of the Midwifery Section; etc.

FIBROID tumours of the uterus are so extremely common, the symptoms to which they give rise are often so distressing—not to say dangerous—and their treatment is, as a general rule, so very unsuccessful and unsatisfactory, that I feel no apology is needed for again directing attention to this subject, although I fear I have but little that is new to add to our stock of knowledge. But as the lives of most of us are spent in endeavouring to improve our therapeutics, and as each year, owing to the frequency of this disease, we have probably all of us many opportunities of testing the various methods of treatment which are from time to time recommended, it may serve some useful purpose to elicit the opinions of the members of this section, so that in the succeeding year we may be stimulated to renewed exertions in this department of practice. I am, moreover, induced to bring this subject forward here, because in our own JOURNAL some few months ago, there appeared a series of short articles giving the experiences of the leading gynaecologists of this country in regard to the medical treatment of these growths; and no one who read those articles could fail to be struck with the great differences of opinion which existed in the minds of the several writers. These opinions are the more to be noted, because it is quite certain that the differences therein expressed cannot be reconciled; there must, then, be some mistake, some error of observation; and it behoves us all, therefore, to be more guarded in our statements, more careful in our investigations, more absolutely precise, if possible, in our diagnosis, and more exact in our therapeutical observations. I allude to the necessity for greater precision in diagnosis, because those who hold—and I, for one, must candidly admit that I am of that number—that, in regard to the absorption or removal of these growths by the administration of drugs in any form, we are utterly and entirely helpless, without a remedy of any kind; those, I say, who hold this view, can only believe that the contrary opinion is based upon an error in diagnosis, or else that the disappearance of the tumour, when that really occurs, is due less to the influence of the drug or drugs which are credited with the cure, than to some natural process which is taking place in the tumour independent altogether of the supposed remedy.

One word as to the nature of these growths, as that is thought by some to have an important bearing on the question of their absorption. It is generally admitted, I believe, that morbid growths partake more or less of the character of the tissues in which they are developed. Hence bones develop bony tumours; fat, fatty tumours; nerve, neuromata; cartilage, enchondromata; and so forth. Those which we are considering are no exceptions. Examined microscopically, fibroid tumours of the uterus present almost the same histological characters as the uterus itself. There may be slight variations in the relative proportions of the several elements, as compared with the proper tissue of the uterus, and different tumours will present different proportions of these; but in the main, there are the same structures, viz., smooth or unstriated muscular fibres, bound together with varying quantities of connective tissue; sometimes one, and sometimes another, of these elements will predominate.

Now, it is thought by some writers that, such being the composition of these tumours, there is nothing remarkable in their gradual absorption and disappearance, any more than there is in the diminution of the uterus after delivery, as in the ordinary process of involution. It is implied, in fact, that the molecular changes are the same in both cases, and surprise is expressed that any one should entertain a doubt on the subject. The fact remains, however, that the great majority of observers do entertain very serious doubts on this question; or perhaps I ought rather to say that they have no doubt at all about it, but are decidedly of opinion that such changes, if they ever happen, are of extremely rare occurrence. I have myself seen many scores of these cases, but I have never yet met with one in which I was able to satisfy myself that any appreciable diminution of the tumour was effected either naturally or as a result of medical treatment. It seems to me, moreover, that the reputed explanation, if it have any foundation in fact, should be capable of almost constant demonstration; that, in short, the cure of fibroid tumours of the uterus ought, if this hypothesis be correct, to be the rule rather than the exception; for we all know that we have

almost complete control over the process of involution; and that, if it be delayed after delivery, we can easily stimulate it into action. Why, then, can we not secure this result in the case of these morbid growths? I think that the reason is, because the explanation itself is faulty, and that we cannot apply known physiological laws to pathological actions. My friend Mr. Spencer Wells, arguing in favour of the disappearance of these tumours on the hypothesis above referred to, speaks of the cellular spaces between the fibres becoming filled with serum, and its subsequent rapid absorption under treatment. I very much question, however, whether this be a true statement of fact. Certainly I have never seen such an infiltration, and though it is conceivable that such a state may exist as the result of certain morbid actions going on in the tumour itself, yet I am satisfied that it is of rare occurrence; and even granting its existence, the utmost, I believe, that can be argued from it is that, though this morbid action may be checked and its serous product be absorbed, yet we should still be no nearer the removal of the tumour, for the solid constituents would remain, and no treatment would be of any avail in effecting their removal. The writer of whom I am speaking expresses great surprise that any one should doubt the fact of the disappearance of these growths, and he can only explain it by referring it to the juvenility or limited experience of the observer. Now, there are many much older men than I who entertain such doubts, men of large experience, too; and I can only say, speaking for myself alone, that many years ago when I was much more confident, and my experience far more limited, I had an honest belief in the efficacy of promoting the absorption of these tumours, which age and experience have entirely dispelled. I now do not believe that there is any known drug which is of the smallest value for the purpose in question, nor any method of treatment by which we can hope to diminish one single atom of the solid constituents of these growths.

But while I express this decided opinion on this head, I am none the less convinced that there is a very wide field for the employment of remedies, and ample scope for the exercise of the greatest skill, both medical and surgical. The removal of the tumour, the arrest of hæmorrhage, the control of the various discharges which often accompany these growths, the combating of systemic symptoms, due chiefly to mechanical causes, and often giving rise to great local distress, all these and many other conditions which commonly afflict the sufferer from a uterine fibroid, will tax the ingenuity, patience, and skill of the most accomplished and expert.

In regard to pain, these tumours are not, as a general rule, what would be called painful, unless they are so large as to cause pressure on neighbouring parts, or unless they are so placed as to project prominently from the peritoneal surface. A patient may have a very large tumour growing into the uterine cavity with little or no pain, but a tumour even of small size growing from the peritoneal surface will often occasion very great suffering. I have generally noticed that pain and hæmorrhage are in inverse proportion the one to the other; and just as, if there be much pain, the tumour will most likely prove to be subperitoneal, so, if hæmorrhage be the prominent feature, the tumour will in all probability be either interstitial—that is, in the wall of the uterus, or, as more often happens, it is submucous, that is, growing chiefly into the uterine cavity. Now, we have not yet arrived at such perfection in therapeutics as to be able to soothe the pain of particular nerves or sets of nerves by the administration of a particular drug; we can only act upon any given set of nerves through the general nervous system, spinal or sympathetic, or by topical application. In the absence of this special knowledge, it seems desirable, and in my experience it has been fairly successful, to apply the anodyne as nearly as we can to the seat of pain. Hence the employment of medicated vaginal pessaries; but, inasmuch as it is no part of the function of the vaginal mucous membrane to digest fats, and as fats without digestion cannot be absorbed, and are apt, moreover, to hinder the absorption of other substances, it is desirable, I think, that we should not use greasy substances of any kind. For this reason, I long ago gave up the employment of the cocoa butter, and I now invariably use, as the basis of the pessary, gelatine and glycerine in the proportion of one part of the former to four of the latter; into this we can put any ingredient we wish, and I know no better anodynes than atropine, morphine, or conia. Other agents of this class may of course be used; and if it be preferred, they may be given either subcutaneously, or by the mouth, or by the rectum. It has seemed to me that, when given *per vaginam*, they are more effective, and certainly do not produce so much constitutional disturbance as when given in the other ways. For the treatment of what I may call mechanical pain, of course mechanical remedies will also be required. I allude chiefly or entirely to external support, for I cannot imagine that any one would advocate the use of instruments internally in the treatment of these cases.

Next, as regards the hæmorrhage, the symptom which, of all others,

\* Read in the Midwifery Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

we shall probably be called upon most frequently to treat. Here there is certainly no one remedy which is applicable to all cases; perhaps I might almost say that there is no remedy which is applicable to any case, for in truth the treatment of this symptom is, as a general rule, most unsatisfactory and disappointing. There is, however, a very general consensus of opinion in favour of ergot, and I certainly know no drug which excels its hæmostatic properties in these cases. I believe that it is of most value in cases where the tumour is more interstitial than submucous; it fails, therefore, not unfrequently in the very cases where it is most needed, for it is in the submucous varieties that we get the greatest amount of hæmorrhage. The cause of this failure, or rather of this partial success, is apparent when we consider that the vessels are larger and more numerous in the substance of the uterus than in its mucous surface; and further, the special action of the drug is greater in the substance of the uterus than in its mucous lining; in the one case, it can control blood-supply by diminishing the calibre of large vessels; in the other, the tissue to be acted upon, viz., the capillaries in the mucous membrane, lie, as it were, outside the range of its action.

In the great majority of cases, however, hæmorrhage, especially when it occurs to any extent, is not merely of mucous origin; still less is it solely interstitial, but it comes from both sources, and hence it is that a combination of ergot with any purely astringent hæmostatic answers better than either singly. Moreover, in consequence of the great losses sustained, and the necessary impoverishment of the blood which remains, anæmia more or less marked is sure to follow: chalybeates, therefore, in some form or other seem plainly indicated. Hence the rule with me, in the great majority of cases, is to administer ergot with the peracetate of iron. I find this combination the most generally successful; but iron alum, or any other astringent preparation of iron, will probably answer as well. I need not particularise other forms of hæmostatics, for their name is legion; but I very much question if their value be at all proportionate to their number or variety. In many cases, none of them will suffice; all are equally ineffectual. Then it may be necessary to resort to topical applications, and I know none which is so effective as the small solid stick of anhydrous sulphate of zinc (No. 5 size), first introduced into practice by Dr. Braxton Hicks. I greatly prefer this to the use of fluid injections into the uterus, as I believe it to be fully as useful, and far less dangerous. Through the speculum it may, without any difficulty, be passed quite up into the uterine cavity. The plan recommended by Mr. Baker Brown of freely incising the cervix for the purpose of curing the hæmorrhage, I have on several occasions tried, but I cannot say that I have ever seen any good result from it.

It is not, however, of the merely palliative, still less of the supposed curative drug-treatment of these tumours, that I wish more especially to speak; for I have not over much confidence in the one, and literally none at all in the other; but I am anxious to advocate more frequent and more decided resort to operative interference in these cases under a definite plan and system. I believe that we have it in our power, more than is commonly supposed, to rid our patients of these growths. I have not time now to consider the question of the subperitoneal class. I would merely say, in passing, that in my opinion many of these might be attacked which are now left alone to the great distress of the patient; and I cannot help thinking that, with our rapidly diminishing mortality after ovariectomy, due in great measure to the knowledge we are gaining from daily accumulating experience, the time will come, and is fast approaching, when we shall be fully justified in attempting the removal of many of these growths by abdominal section. But, in regard to the two other varieties, I am convinced that much more ought to be done than has been the rule hitherto. I am not going to advocate the process of gouging, or of enucleation, or of destruction by the actual cautery. I have never attempted either operation, and I do not think I ever shall; but I have so frequently seen attempts made by Nature to extrude these growths, even when they were hardly within the uterine cavity at all, and so often has she failed through the want of some artificial assistance, that I am satisfied that we shall derive far more satisfactory results than we have hitherto done, if we direct our thoughts to the question, How can we best aid Nature in the attempt to expel the tumour? We need not try at once to remove the tumour by one operation, unless there be a reasonable prospect of success; but we ought, I contend, to recognise it as a rule always so to prepare the parts that no obstruction which we can remove shall stand in the way of the extrusion of the mass. Let me relate a case in point, which will serve to illustrate my meaning, and, at the same time, will convey a fair idea of the method which I am advocating.

Mrs. C., aged 34, married eleven years, without issue, was admitted under my care into the Hospital for Women, January 13th, 1871. She had for years been suffering from excessive menorrhagia, which amounted

at times to a regular flooding. On examination, a hard globular tumour could be felt about a hand's breadth above the pelvic brim. *Per vaginam*, the infravaginal portion of the cervix was small; the os was circular and so small as only to admit the sound with difficulty, but that instrument entered the uterus for about four inches. At the level of the internal os the uterus could be felt greatly enlarged; and, by pressing on the tumour externally, the enlargement of the uterus was found to be due to it. The cervix was dilated with tangle-tents, and it was then found that the tumour was of the interstitial kind; that is to say, it was embedded in the whole anterior and right sides of the uterus, and extended from cervix to fundus; it, however, projected a good deal into the cavity of the uterus. Subsequently I divided the anterior lip of the cervix, cutting a little into the tumour itself, but the bleeding was so great that I could not do much in this direction. Three weeks afterwards, I divided the cervix on each side; there was less hæmorrhage, and I made the incision as free as I could. The patient then left the hospital, and returned in three months. I then found that the object which I had in view—viz., the favouring of the descent of the tumour by removing the obstruction presented by the small contracted os—was being surely accomplished; for, whereas at first the os only admitted the sound with difficulty, it now admitted one finger easily, and the tumour itself could be felt presenting. I accordingly attempted the next stage; viz., the separating the tumour from its attachment as far as the finger could reach. My object in this was gradually to get the tumour pedunculated and forced down by the uterus towards the orifice. The latter action I assisted by the continuous administration of ergot from the time of the first operation. In three weeks' time, the os became dilated to the size of a crown-piece, and the tumour was protruding into the vagina. I therefore again passed two fingers into the uterus, and detached a still larger portion of the tumour, leaving, in fact, a comparatively small attachment at the upper part of the body and fundus uteri. At the present time the os is perfectly open, the vagina is nearly filled with the protruding tumour, which has come down so low that not more than half of that which was above the pelvic brim can now be felt there, and in the course of a few weeks I shall make the final operation by still further separating the attachment of the tumour, and removing it with the wire *écraseur*.\*

Now, when I first saw this patient, it would be difficult to imagine a case more unlikely to be attended with success in regard to any operative interference. Here was a tumour completely embedded in the uterine wall, the cervix unaffected by it, and therefore small, and the os quite as contracted as in a healthy virgin uterus. Yet now the tumour has been brought, partly, perhaps, by nature, but chiefly by art, completely within reach, and though it is not yet actually removed, it shortly will be, and I believe with little or no difficulty. I think, then, I am justified in saying that patience, perseverance, discretion, and a good use of our fingers, will enable us to accomplish a great deal more in the cure of cases of this kind than has been hitherto generally admitted. But in order to do this, we must bear in mind the following propositions, upon the truth of which the whole practice is based.

1. These uterine tumours are to be regarded as essentially foreign bodies.
2. Nature's method of dealing with such foreign bodies, when fair play is allowed her, is to expel them.
3. In order to do this, a dilated os and uterine contraction are essential.
4. Where these are wanting, it is the duty of the physician to remedy it.
5. In order to do this, the circular fibres of the cervix uteri should be freely divided in several directions, and subsequent contraction of the uterus should be promoted by every means in our power.
6. Both these measures will be greatly aided by subsequent detachment of the tumour, making it more and more like a foreign body.

Now, it may be said, perhaps, that there is nothing new in all this: that division of the cervix, separation of the tumour from its attachments, and the attempt to secure its expulsion by exciting uterine contraction, have each been tried and recommended in turn. It is not, however, any one of these that I now advocate, but a combination of all three, and I am not aware that any such combination has been recommended hitherto. Each step in the process has its proper function, and the operation is not complete unless all are included in it. Our first thought should be to prepare the passages for the expulsion and removal of the growth; when this is accomplished, we should try to make the tumour as "foreign" as we can, by separating its attachments as far as can be reached; and throughout the treatment we should aim

\* This tumour has, since the paper was read, been successfully removed, and the patient discharged cured.

continuously at securing its expulsion by the slow but sure process of uterine contraction. Either of these methods singly is almost certain to fail, as I have found again and again; but I believe that a large number of cases, hitherto regarded as incurable, may be made amenable to the plan now recommended, if only it be judiciously and perseveringly carried out.

## ON A REGULATED TEMPERATURE IN THE TREATMENT OF DISEASE, ETC.

By ALEXANDER ROBERTSON, M.D.,

Physician to the Town's Hospital and City Parochial Asylum, Glasgow.

BEFORE entering on the latter and main part of my subject, it is requisite that I should describe the general plan on which the apparatus is constructed by means of which an equable and regulated temperature can be applied without difficulty to different parts of the body. When the probable advantage of the application of heat so regulated first occurred to me, I saw at once that no suitable instrument existed by means of which it could be carried out. After considering whether heated air or steam could be controlled so as to accomplish the end in view, and having found this quite impracticable, I turned my attention to water as a medium through which the object might possibly be attained. The remarkable properties of vulcanite or vulcanised India-rubber—its lightness, its softness, its moderate elasticity, and particularly its power, on the one hand, of resisting heat higher than the boiling point, and, on the other, cold greater than that of ice—at once pointed it out as a substance out of which appropriate apparatus might be constructed. Accordingly, the various articles which I have designed are made of this material. They are all formed on the same plan. They consist of bags divided into two or more compartments, and have two tubes of convenient length attached to them, the one of which serves for admitting, the other for discharging the water. They may be worked either in connection with an ordinary tin or other vessel with a tap at the bottom, or, when no such vessel is at hand, they may be used on the principle of the syphon. In the former case, the end of the inlet-pipe is attached to the tap, and the stopcock opened. The water passes through the compartments, in its course raising or lowering the temperature of the bag, as required; and is then discharged by the outlet-pipe. When an exact heat is wanted, a bath-thermometer is placed in the vessel containing water; and by means of it any person who can read figures can maintain the temperature of the water to be circulated to within two or three degrees of a required point, as long as is necessary. Five different instruments have been

designed, respectively for the chest or abdomen, the spine, the head, the uterus, and the neck; but the one for the neck or throat has not yet been constructed. I need scarcely say that their shape might be varied still further to suit other parts of the body.\*

As yet, I have had leisure to test the action only of the chest and uterine bags. Two series of observations have been made with the chest one. They were instituted to determine the effects of an uniform high temperature, and to ascertain the results of renewing the temperature so soon as the heat of the instrument should have fallen to nearly that of the body in a healthy condition. The one series was carried out by myself, and the other by my assistant, Dr. Morrison. My own will be the first described.

It consists of three groups. The first includes cases in which the bag was applied to the skin, nothing intervening, and therefore brings out the effect of dry heat. The second and third comprehend cases in which it was applied in the one instance outside a fomentation, in the other outside a poultice, and illustrate the action of uniform heat associated with moisture.

It is perhaps necessary to observe, that in no case were there more than two pairs of blankets on the bed, these being, as a rule, well worn; so that it may be clear that the action on the skin, afterwards to be described, was in nowise assisted by the amount of clothing.

**GROUP I. Cases treated by the Bag alone.**—Twelve patients, ten males and two females; the ages ranged from 18 to 51, the majority being from 30 to 50. Seven suffered from bronchitis, mostly complicated with emphysema; one laboured under phthisis pulmonalis; one had acute general tuberculosis; one pleurisy with bronchitis; two cardiac disease; and one lumbago. In one of the bronchitic cases, the attack was acute and recent; the others were chronic, with exacerbations. The case of phthisis pulmonalis was in the third stage; those of lumbago and tuberculosis were severe. The bag was applied half an hour in two cases; an hour in eight; an hour and a half in one; two hours in one case. The temperature of the water circulated was 130 to 135 deg. in one case; 135 to 140 deg. in one case; 140 deg. in six cases; 145 to 150 deg. in one case; 150 deg. in three cases.

**Effects.**—*a. Skin.*—In six cases a very free general perspiration occurred, both on the trunk and on the extremities. It appeared usually about a quarter of an hour or twenty minutes after the circulation of the water had been commenced, and continued as long as the bag was applied, persisting in two cases during the entire night afterwards. In four patients the sweating was moderate. In two of them it was more decided on the trunk than on other parts; in the other two it was most marked on the extremities. In two patients—the cases of constitutional syphilis and tuberculosis—no sweating occurred at all. The surface to which the bag had been applied was red, but not so much so as after the mustard, or mustard-and-linseed poultice. In two cases in which the water had been circulated at 150 deg., several vesicles, about the size of a penny, appeared on the skin shortly after the removal of the bag.

*b. Pulse.*—In five cases there was a reduction, viz., of 10, 8, 6, 4, 4, beats per minute; in five there was no change; in two there was an increase—one, the case of phthisis pulmonalis, was 14 higher; the other one, the case of constitutional syphilis, was 8 higher. When the pulse became lower, it was usually fuller, and the decrease was generally associated with free perspiration.

*c. Temperature.*—In seven cases the observations were made in the rectum; in three (females) in the axilla. In the former, the thermometer was retained for at least five minutes; in the latter, for a quarter of an hour, *in situ*. In two of the rectal cases there was no change; in two there was a decrease respectively of 1 deg. and 0.2 deg.; in three there was an increase of 1.04, 0.4, and 0.2 deg. Two of the axillary cases continued the same; in the other one there was an increase of 0.4 deg. In two of the patients, owing to omission, the observations had not been registered. It was observed that free perspiration was associated either with a reduction or with no increase of temperature; on the other hand, an elevation concurred with little or no moisture on the skin.

*d. Respiration.*—The condition of this function has been recorded only in seven cases. In five of them there was a reduction of from two to four per minute; viz., from 34 to 30, 22 to 18, 18 to 16, 34 to 32, 23 to 21; in two there was an increase—in the one from 26 to 27; in the other from 21 to 22. Here, again, a reduction in the number of respirations was associated with free perspiration. One of the patients in whom there was increase in the rate, was the syphilitic girl, who did not perspire; the other patient suffered from cardiac disease in a severe form, and in her perspiration was moderate.

Fig. 1.—Section of Chest or Abdominal Bag (about a fourth size).

*a a* Compartments; arrows show course of water. *b b* Inlet and outlet pipes, each three feet long. *c c* Small taps, two feet from bag. *d d* Vulcanised cloth, to which compartments are cemented; these being covered with flannel.

\* Continued from page 609 of last number.

\* These apparatus have been made by Messrs. Mackintosh and Co., India-rubber merchants, Manchester.

*c. Patients' Statements.*—First, I would remark that, of course, I do not place so much reliance on these statements as on the exact observations which I have just detailed, even though I cautioned the patients against giving me an exaggerated account of their sensations or conditions. They all thought themselves benefited by the application of the bag. A number spoke very strongly in favour of it, especially when contrasted with the mustard poultice. In most cases, I was satisfied that they had really experienced relief from the feeling of oppression and pain they had been previously suffering. Three patients, however, did not seem to have improved. They were the cases of syphilis, tuberculosis, and cardiac disease already specially noticed. As a rule, it was in those cases where the skin acted most freely that the benefit obtained was the clearest.

**GROUP II. Cases treated by Bag outside a light Linseed-meal Poultice.**—Eight applications were made to seven patients, two males and five females; their ages were between 31 and 46, except in one, who was 67. Four suffered from chronic, and one from acute bronchitis; one from phthisis pulmonalis, and one from renal disease with dropsy. The water was circulated in six for an hour; in one for an hour and a half; in one for eighteen minutes. In all cases the applications were made to the front of the chest. The temperature of the water circulated was 155 deg. in three cases, 160 deg. in two, 165 deg. in one, 170 deg. in one. The temperature of the poultice on application and on removal was noted in five cases. In all there was a reduction, usually of about ten degrees—for example, from 130 to 120 deg.

*Effects.*—*a. Skin.*—In seven cases very free perspiration occurred; in one it was moderate; and in three it continued, though in a less degree, all the following night. As has been stated, one application was only for eighteen minutes. This was in a case of phthisis pulmonalis, in which it did not seem desirable that the perspiration should be further promoted.

*b. Pulse.*—In two it continued the same; in two there was an increase, respectively of 14 and 2; in three there was a decrease—viz., 14, 10, and 5; in one no rate was taken. In three instances the pulse was fuller, besides being slower; in one case of phthisis pulmonalis it was weaker. In the case where an increase of 14 occurred, it was 60 and weak at the commencement, 74 and fuller at the close of the observations.

*c. Temperature.*—In two the axillary temperature was the same; in one, it decreased 0.4 deg. Of three rectum observations, in one there was no change, in one there was a decrease, and in one an increase, respectively of 0.4 deg. Where the increase occurred, the temperature was 99.6 deg. before the poultice was applied.

*d. Respiration.*—In five there was a decrease, viz., 26 to 24, 26 to 22, 31 to 27, 31 to 29, 42 to 38; in two there was an increase, respectively from 17 to 18, and from 18 to 23; in one there was no difference. The increase of 5 was in the case of phthisis pulmonalis.

*e. Patients' Statements.*—All expressed themselves as more or less relieved, some very decidedly so, except the phthisical woman, who thought she felt weaker.

**GROUP III. Cases treated by Bag outside Fomentation.**—The fomentation consisted of two folds of flannel wrung out of hot water. Nine applications were made to eight patients, four of whom were males and four females. Their ages were from 21 to 68. Three laboured under bronchitis, four suffered from Bright's disease of the kidney, and one from diuresis associated with general dropsy. The disease in each case was severe. In eight cases the water was circulated for an hour; in one for an hour and eighteen minutes. In two cases of renal disease, the fomentation was applied to the loins; in all the others, to the front of the chest. In four cases the water was circulated at 165 deg., in three at 170 deg., in one at 160 deg., in one at 150 deg. The temperature of the fomentation-cloth varied on application from 120 to 125 deg.; at the close, from 115 to 121 deg.

*Effects.*—*a. Skin.*—Three patients, two suffering from renal disease, and one from bronchitis, perspired very freely; one with renal disease perspired moderately; no perspiration occurred in three cases—the one renal, the two others bronchitic. The patient with diuresis, to whom two applications were made, with an interval of forty-eight hours, perspired freely on both occasions; not, however, during the application of the fomentation, but two or three hours afterwards. The renal case where there was no sweating, was in an advanced form, and the patient was suffering from obstinate diarrhoea.

*b. Pulse.*—In five cases there was a reduction, viz., 4, 8, 8, 12, and 14; in two there was an increase, 4 and 8; one continued the same.

*c. Temperature.*—In three cases (males) the observations were made in the rectum. In one of these there was no change; in the other two there was an increase from 99.6 to 100 deg., and from 98.2 to 99.4 deg. Five were axillary observations, and in all these there was an increase, viz., 99.4 to 99.8 deg., 99.2 to 99.6 deg., 99.4 to 100.6 deg., 98.6 to

99.8 deg., 97.6 to 98.8 deg. The increase of more than 0.2 or 0.4 deg. was in those cases where perspiration did not occur during the application of the bag.

*d. Respiration.*—In six there was a decrease—viz., 1, 2, 3, 4, 8, 8; in two an increase, respectively of 2 and 3; one remained the same.

*e. Patients' Statements.*—With three exceptions, all said that they had been relieved, and were free from the feeling of pain and oppression which they had previously suffered. Two of the exceptions were patients with renal disease, in whom no perspiration was produced, and both of them felt weak after the circulation of the water; one—a bronchitic patient—did not observe any change.

In a previous part of this paper I recorded the effects of a mustard-and-linseed poultice applied to the chest of a healthy boy. For the purpose of contrasting them with those which might be produced by an equable heat, two days after the poultice, when the boy was in equally good health, I had the water-bag applied, and noted the results of its action. In all respects the general conditions were the same, save that the temperature of the room was three degrees lower than in the case of the poultice. The state of his system before its application was as follows: pulse 83; skin soft; soles of feet slightly moist; respiration 23; temperature of rectum, 99.4 deg. Water was then circulated at 135 deg. for thirty-three minutes—the same length of time that the poultice was continued—nothing intervening between the bag and the chest. The following was his condition at the close; pulse 81; perspiration standing in large drops on the face; the whole trunk of the body, palms of the hands, and soles of the feet, very moist; the arms and back of the legs moist, the front of the legs less so than any other part. The perspiration was distinct on the face fifteen minutes after the circulation of water had been commenced. The respirations were 23. The temperature of the rectum was 0.1 deg. higher. The surface of the chest on which the bag rested was red; not so much so, however, as after mustard. The poultice, he said, was much sorer than the bag. He was very restive under the former, but lay quite quiet while the water was being circulated; the difference in this respect was very striking.

I also instituted another series of observations in order, as far as possible, to determine the value of renewing the temperature of the medium—whether that were the bag alone, or either the poultice or the fomentation with the bag—so soon as its heat should have sunk to nearly that of the body. These observations were carried out with much care by my assistant, Dr. Morrison, in accordance with my instructions.

The mode of procedure throughout the entire series was to warm the bag thoroughly before use by allowing hot water to stand in it for a few minutes, and then displace that water by a fresh supply at a definite temperature for each group of cases. It was then applied, and its contents renewed without removing it from the body, at the same degree of heat three times in the course of two hours—viz., at the end of half an hour, an hour, and an hour and a half. The following is a summary of the results obtained by Dr. Morrison.

**GROUP I. Observations with the Bag alone.**—Temperature of water, 140 deg. Seven patients, five males and two females; the ages were from 37 to 54. Five suffered from bronchitis, one from phthisis pulmonalis, and one from pleurisy with bronchitis. The diseases were all of considerable severity. The application in each case was made to the front of the chest.

*Effects.*—*a. Skin.*—After half an hour, in four cases there was no apparent change, and in three cases there was slight moisture. After an hour, in five cases there was distinct moisture, and in two the perspiration was free. After an hour and a half, in one case it was slight, in three cases very free, and in three cases moderate.

*b. Pulse.*—In two it continued the same; in two it increased in frequency—respectively 14 and 2 per minute; in three it decreased; in one being 8; and two, each 2 fewer per minute. The pulse was fuller at the close in five cases.

*c. Respirations.*—In three there was a decrease—2, 6, 6; in two an increase—10 and 3; one continued the same; and one had been omitted.

*d. Patients' Statements.*—All had experienced relief, especially from the more distressing symptoms; but one, the man with phthisis pulmonalis, added that he felt weak. I quote Dr. Morrison's remarks on this head in regard to two cases; and the entries regarding the others are in similar terms. "1. The statement of the patient was that, during the first half hour, he felt more comfortable, and the defluxion came away more easily. At every application he expressed a feeling of comfort, and, at the end, stated that he could breathe more freely, and had got relief from a sensation of oppression about the chest." "2. Statement of patient was that the pain of the chest was entirely removed, and she felt very comfortable."

**GROUP II. Observations with light Linseed-meal Poultice underneath Bag.**—The temperature of water in the bag on application and at each renewal was 180 deg. It was applied to seven patients: three males and four females, from 38 to 54 years of age. All suffered from bronchitis; and the disease, except in one case, was in a severe form. In all cases the application was made to the front of the chest.

*Effects.*—*a. Skin.*—At the end of the first half hour, slight moisture was noted in six cases; one was perspiring freely; and in one there was no perspiration. After an hour, five were sweating moderately, one freely, and one gently. After an hour and a half, five perspired very freely, one freely, and one moderately.

*b. Pulse.*—In all cases there was a decrease: in two of 10, in three of 8, in two of 6. In five patients it was fuller at the close; and in one of these, where it was weak and intermittent at the application of the bag, it is recorded as being full and regular on its removal.

*c. Respiration.*—In all these there was a reduction; in four of 2, in one of 3, in one of 4, and in one of 6 per minute.

*d. Patients' Statements.*—All said that they had derived benefit from the application. I quote two in illustration. 1. "Statement of patient was, that she had now no pain, felt easier and more comfortable, and her cough was very much relieved." 2. "Statement of patient was, that his breathing was very much freer, and his chest was 'lighter.'"

In order to ascertain if the heat of the poultice was really raised sufficiently by simply changing the water, I had also desired Dr. Morrison to note its temperature five minutes after the first, second, and third renewals in two cases for each time. He found, on all occasions, that it was never lower than 121 deg., and was sometimes 125 deg., except in the first case which he examined, where it was only 110 deg. after the first renewal; but this was probably due to some mistake, as the others were so much higher. The poultices were applied at an average temperature of 128 deg.

**GROUP III. Observations with Fomentation and Bag.**—The fomentation consisted of a double fold of flannel wrung out of hot water. The temperature of the water at each renewal was 180 deg. It was applied to seven patients—three males and four females, aged from 41 to 70. Six suffered from bronchitis—two in a moderate, and three in a severe form; one laboured under lumbago. In the case of lumbago, the fomentation was applied to the lumbar region of the spine, and in the others to the front of the chest.

*Effects.*—*a. Skin.*—At the end of half an hour, there was slight moisture on the surface generally in all cases. At the end of an hour, in four it amounted to moderate perspiration. After an hour and a half, there was free, or very free, sweating in five patients, while in two it was present only in a slight degree.

*b. Pulse.*—In all cases there was a decrease: in one of 12, in one of 10, in one of 8, in one of 6, in two of 2, and in one of 1 per minute. In five patients the pulse was of better volume; in two there was no change.

*c. Respiration.*—In all there was a reduction: in one of 4; in each of the other two cases, 9.

*d. Patients' Statements.*—Greater or less relief had been experienced by every one. I again quote two entries in illustration. 1. The "statement of the patient was, that she had got relief from the difficulty of breathing, and that the pain was gone." 2 (Case of lumbago). "Statement of patient was, that the pain was entirely gone."

In this group the average temperature of the fomentation on application was 130 deg. As with the poultices, I thought it desirable to test whether the heat of the fomentation-cloth was raised sufficiently by merely changing the water. Accordingly, observations were made five minutes after each renewal, by inserting the thermometer between the folds of the flannel, which showed that the temperature was restored to as about as high a point as the first—the range being from 126 to 130 degrees.

[To be continued.]

## EXTRACTS FROM MY NOTE-BOOK.

By T. R. JESSOP, F.R.C.S.,

Surgeon to the Leeds General Infirmary.

### 1.—*Traumatic Neuroma, causing Paralysis: Rapid and Complete Restoration of the Function of the Nerve after Removal of the Tumour.*

THE following case affords an interesting example of the rapidity with which, under favourable circumstances, a divided nerve will reunite, even when there has been considerable loss of substance. The ready manner in which the nerve resumed its functions, after these had been in complete abeyance during nine years, gives to the case additional physiological value.

Emma Ross, aged 19, residing at Bramley, was admitted into the Leeds General Infirmary on February 9th, 1871. When ten years old, she cut the inner side of her wrist with a glass bottle. This was followed immediately by loss of sensation on the inner side of the hand, and by diminished power in the entire hand. When, after many weeks, the wound had at length healed, the resulting scar remained painful and tender. At times, the pain was so great as entirely to prevent sleep, and was not always confined to the seat of injury, but occasionally extended up the forearm and arm, and frequently downwards through the hand and two inner fingers. During the few months immediately preceding her application to me, the pain had increased in intensity.

The cicatrix was situated about two inches above the right wrist, and extended across the half of the anterior surface of the forearm; it was hard and very painful on pressure. The hand, as compared with the left, was thin and wasted. The muscles which should have formed the balls of the little finger and thumb had disappeared; and between the metacarpal bones, both back and front, were deep hollows. Over the inner third of the hand, the whole of the little and the inner half of the ring fingers, the skin had completely lost its sensibility, and sensation was imperfect over the radial half of the ring finger. The movements of the hand were so feeble that the limb was of little use.

On the day of admission, February 9th, the ulnar nerve in the neighbourhood of the cicatrix was laid bare to the extent of about an inch, by an incision along the inner border of the forearm. Just where it traversed the cicatrix, the nerve presented a globular enlargement of the size of a pea. This, together with about half an inch of the involved nerve in its entire thickness, was removed, when the divided ends immediately retracted. In order to approximate the cut ends of the nerve, it was found necessary to flex the hand upon the forearm. Whilst the hand was so held, the ends of the nerve were brought accurately together by means of a fine carbolised silk suture, and so retained. The operation was performed, and the wound dressed, in accordance with the strictest antiseptic principles.

For three days after the operation, there was considerable pain along the course of the ulnar nerve, as high as the middle of the upper arm, which was relieved by repeated subcutaneous injections of morphia. The wound healed by first intention.

On February 17th, there was the first indication of returning sensation on the ulnar side of the little finger; and the patient now complained of severe pains shooting from the tips of the little and ring fingers to the wound. From this time the pain gradually diminished, whilst sensation extended and increased.

On February 24th, sensation seemed to have fully returned everywhere except at the extreme tips of the two fingers, and the pain had all but ceased. The hand was now released from its flexed position, and gentle passive motion of the wrist commenced.

On March 11th, as there was inability fully to extend the wrist, the limb was bound down upon a straight splint. On March 20th, she was made an out-patient, and ordered to attend twice a week for galvanism of the muscles of the hand. On April 20th, she could use the hand well; had no pain; could feel perfectly everywhere, except at the tip of the little finger, which, on examination, was found to be covered with a thick layer of cuticle; and the muscles of the hand showed signs of returning development. She can now (November) use the hand for all purposes; the muscles have to a great extent re-formed, but the right hand is still somewhat thinner than the left, and sensation is still wanting at the tip of the little finger, though it is everywhere else perfect.

## CLINICAL MEMORANDA.

### RECOVERY AFTER SWALLOWING A LARGE QUANTITY OF CHLORAL.

A SHORT time since, an anæmic middle-aged married female, whilst suffering from facial neuralgia, swallowed at one draught a recently prepared syrupy solution of chloral hydrate, which contained over 100 grains of that drug. She immediately complained of "intense burning pain in the throat, gullet, and stomach"; and when I saw her (about three-quarters of an hour subsequently), she was screaming and almost convulsed with agony—so much so, that it was with the greatest difficulty she could be restrained from throwing herself out of her bedroom-window into the road. Her pulse was small and very rapid; the countenance was livid and bathed in sweat; an odour of chloroform was plainly perceptible in the breath; and no trace of narcotism had been observed, even for a moment. After an ineffectual attempt to bring on vomiting, I injected hypodermically half a grain of morphia over the epigastrium, and directed milk to be freely given. On visiting

her in three hours' time, I found her somewhat relieved, and accordingly injected another half grain of morphia, and suggested the cautious use of stimulants with the milk. On the following morning she was free from all pain of any description, though very weak, and has since done well; a slight return of neuralgia being at once checked by another employment of the hypodermic syringe, and ferruginous tonics.

The usual hypnotic effects of the chloral were here "conspicuous by their absence" from first to last; no drowsiness even, much less sleep, having set in during the period of its elimination from the system: yet in a previous neuralgic attack, twenty grains only had procured a good night's rest for this person. I can vouch for the amount, as well as the goodness, of the chloral taken by her; and think that, as deaths have been reported after the administration of 60, 45, and even 25, grains of this remedy, she may be deemed fortunate in escaping so readily.

BENJAMIN BROWNING, L.R.C.P.L., etc.

Littlebourne, Kent, November 15th. 1871.

#### MODE OF DEATH IN CHLOROFORM POISONING.

I ADMINISTERED chloroform to two guinea-pigs on November 12th, 1871, and as soon as anæsthesia was complete, I opened the thorax. Respiration had completely ceased, and the lungs were collapsed; the hearts were beating regularly and forcibly. I sprinkled the pericardium of one heart with chloroform without detecting any effect upon the cardiac pulsations; the other heart I did not meddle with. In three minutes the cardiac contractions became feeble, more frequent, then intermittent, then fluttering and imperfect, and finally ceased. In the guinea-pig on whose heart I dropped the chloroform, pulsations entirely ceased three minutes and twenty seconds after I had opened the thorax; in the second case they were perceptible for exactly four minutes.

S. MESSENGER BRADLEY, Manchester.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### LONDON HOSPITAL.

##### DEATH DURING THE ADMINISTRATION OF CHLOROFORM.

AN apparently healthy man, aged 53, was admitted about 3 P.M., having had his foot crushed by a piece of iron falling on it. It was found necessary to amputate the first toe, and the patient was given the choice of taking chloroform or not. He hesitated for some little time, but at length, without being pressed, he said he should prefer to have it administered.

The chloroform was given by the house-surgeon on a double fold of lint, and for about five minutes seemed to produce no effect. The patient then suddenly became much excited, and the administration of the chloroform had to be desisted from, as the gentleman giving it was obliged to lend assistance to restrain the patient. He continued excited for about two minutes, and then became quiet. He screwed up his eyes when the conjunctivæ were touched. The operation was now commenced, and he winced at the first prick of the knife. The gentleman who from the commencement of the proceedings had kept his hand on the pulse, now said that it was beating very feebly, and almost immediately after that it had stopped. The man breathed more than once after the heart and pulse had ceased to be felt. Artificial respiration, on the Silvester plan, was immediately had recourse to; the tongue was dragged forward; the patient was well splashed with cold water, and flipped with a wetted towel. The interrupted current was almost immediately applied from the nape of the neck to the diaphragm. All these efforts were most strenuously made for about twenty minutes, without producing any evidence of life. No chloroform had been administered from the time of the patient becoming excited.

It was subsequently elicited that the patient had been an intemperate man, and that some years previously he had taken chloroform for the reduction of a fracture.

The necropsy was made on the following day by Dr. Sutton. The body was very well nourished; the skeleton large and well developed. There was a moderately thick layer of subcutaneous fat beneath the skin of the abdomen. The pleuræ were healthy; the lungs normal, but very much congested. The mucous surfaces of the larynx and trachea were somewhat congested, but they contained no foreign body. The

pericardium was healthy. The heart weighed 14½ ounces. The left ventricle was flaccid; its cavity seemed slightly dilated, and the muscle was soft and very friable. The left auricle and the mitral orifice were healthy, as were also the aortic valves and aorta. The right ventricle was distended with blood, but was otherwise healthy. The liver weighed 6 lbs. 2 oz. On section, it was homogeneous-looking and soft—evidently fatty. The spleen was natural. The kidneys showed evidence of great venous congestion. The stomach contained a little partially digested food. The mucous surface was very much ecchymosed in parts, but was otherwise healthy. The brain was healthy. The muscle of the heart was examined microscopically, and it was found that the transverse striæ were very indistinct. The fibres were granular, and contained some fat-globules.

#### HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

##### NOTES ON CASES OF DISEASE OF THE NERVOUS SYSTEM.

(Under the care of Dr. HUGHLINGS JACKSON.)

*Voluntary and Automatic Movements.*—In the last note (October 29th, 1870), remarks were made on the fact that the utterances to which speechless patients are usually limited are "yes" or "no", or both. They lose all speech except the most *automatic* propositions; or, in physiological language, the most automatic movements of the speech series. Sir Thomas Watson has observed that the speechless patient may be able to use the word no very readily in reply to a question, when he cannot utter it, when told to say "no". This was marked in the case of a man 51 years of age, who had been for more than nine years paralysed on the right side, and speechless, with the exception that he could utter the word "no"; and not only could he utter it, but he could "propositionise" with it—he could reply "no" correctly; but he could not say "no" when told to do so. The class (this was at the London Hospital) were informed that the patient could utter this word; but when he was told to do so he only brought out a mumbling noise. The utterance of the word was easily obtained from him by asking the preposterous question, "Are you a hundred years old?" In the case of a young woman recently in the Hospital for the Epileptic and Paralysed, for loss of speech and hemiplegia of the right side (the supposed result of embolism; there was a mitral obstructive murmur), this peculiarity was very striking. Thus at one visit she was told to say "no", and could not. Directly afterwards, Dr. Hughlings Jackson observing that she had a book on her lap, asked if the patient could really read. Hearing this, the patient herself looked up, and said "No, no, no." She was again told to say "no"; she could not. The nurse having observed this peculiarity in another patient, said, "Are you a hundred years old?" The response was, "No", with a smile. Once more the patient was asked to say "no", but again she failed. This patient had, it would seem, the power to utter the word automatically, but not voluntarily. It must be added, that many times in her ordinary "conversation" she said "no" when she meant "yes".

In some cases the patient has no difficulty in saying "no". Thus there is in the London Hospital an old woman who can utter only the words "yes" and "no", and "titty", "titty"; and another old woman who has both these words and the utterance, "I'm very well", or "Very well". Each of these patients can say "no" when asked. There are three degrees in which this word is uttered by speechless patients: (1), and lowest, in an interjectional manner; (2) in this way, and also as a reply; (3) in both the former ways, and when they wish to utter the word for the sake of uttering it.

Such facts seem, at first glance, to be mere curiosities; but they are very significant. The experiments which disease makes give us hints as to what is fundamental in the method of nervous action. There are other facts of the same order. The most striking is, that intellectual language may be lost when emotional language is conserved. The former are the more voluntary, the latter the more automatic, movements of language. In defects of intellectual language itself, speech suffers more than pantomime—which mode of voluntary expression almost runs into the automatic exhibition of states of feeling by gesticulation: nay, in the most "voluntary" part of intellectual language—in word processes themselves—we see the same thing: we find that a patient ejaculates when he cannot "speak" these ejaculations; cannot repeat them.

Dr. Hughlings Jackson thinks these utterances are the result of action of the right side of the brain, which side is not damaged in cases of loss of speech. He supposes, indeed, that the patient has remaining on this side all the words he ever had in an automatic form—that, although speechless, he is not wordless; for, although he cannot "propositionise", he can, since he understands what we say to him, receive propositions.

From the facts of cases of speechlessness, and from observations on cases of hemiplegia, he draws the conclusion that, in "destroying lesions" of the nervous system, movements suffer the more as they are voluntary, and the less as they are automatic. In future notes it will be pointed out that in degrees of hemiplegia, from lesions of different gravity, there is a twofold manner of increase of the paralysis—(1) greater palsy of the voluntary parts, and (2) a further spreading in range to parts more automatic. Dr. Hughlings Jackson infers that, both in physical and mental processes, healthy nervous action spreads from the automatic to the voluntary; that the spreading is in a compound manner; that, with increasing power of the voluntary movement, there is greater range in automatic movement. The words "voluntary" and "automatic" are used without prejudice; and, to a more or less extent, the terms "special", "independent", etc., may replace the word "voluntary". The word "voluntary" would not be used were it possible to find one with less misleading implications. The word has a double meaning. It is used psychologically in discussions on the nature of the Will with which physiological inquiries have no direct concern. It is used also physiologically as a name for those movements which have at once great speciality and also great independence of other movements. A voluntary part differs from an automatic part in two ways; (1) in having a greater number of different movements (more complex space coordinations); (2) in having a greater number of different intervals (more complex time coordinations). It is implied that there is no abrupt demarcation between the two kinds of movements.

## GENERAL HOSPITAL, NOTTINGHAM.

### CASES OF HYDROPHOBIA: WITH REMARKS.\*

By GEORGE ELDER, M.B., Junior House-Surgeon to the Hospital.

**CASE I.**—On the evening of February 18th, 1870, W. Wadsworth, aged 27, was admitted under the care of Dr. Robertson and Mr. White. Eight weeks before admission, a strange dog had bitten the patient in four places; viz., one on the left thumb, and three on the face. Nothing was applied to the wounds. From the period of infliction of the bites until February 16th, the patient went about his work as usual; but on the evening of the latter mentioned day, he felt "out of sorts." Although the feeling of *malaise* experienced on the evening of the 16th was somewhat increased when the patient got out of bed next morning, yet, referring his sensations to a "simple cold," he went to work. During the day, sharp paroxysmal pains were felt in the cicatrix upon the left thumb. On the morning of the 18th, whilst he was eating his breakfast, occasional spasms were excited, combined with a difficulty in swallowing.

On admission, the patient, a powerfully built man, had an anxious, hopeless expression. The eyes were staring; the conjunctivæ were slightly injected. On offering him a cup of water he shuddered, and on attempting to drink, his body was thrown into severe spasms, almost tetanic in character. Between the spasms, the act of respiration was of a peculiar sighing nature, inspiration being greatly prolonged. Great thirst was complained of, yet the tongue was moist. The mental faculties were unclouded, and the patient talked freely of his malady, seemingly fully alive to the awfulness of his position. The scars on the face and thumb betrayed no abnormality. After placing the patient in a ward detached from the main building, so as to avoid as much as possible disturbance from noise, etc., a drachm of tincture of opium was administered *per rectum*, but not retained. On the morning of the 19th, it was noted that the patient had not slept during the previous night; otherwise, his condition was much the same as on admission. By the direction of Dr. Robertson, two quarter-grain doses of acetate of morphia were hypodermically injected at an hour's interval, certainly with the effect of quieting the mind of the patient, but not of alleviating the spasms. Three hours after the second injection of morphia, it was decided at a consultation of the honorary staff to give chloral hydrate a trial. Accordingly, between 4.30 and 11 P.M., two doses of a drachm each were injected into the rectum and retained. After the second dose, the actions and conversation of the patient were those of a man intoxicated, and so much was the hyperæsthesia of the body diminished, that liquids, without much discomfort, were several times drunk. Shortly after eleven o'clock, the staff again met and concluded, when it was decided with one dissenting voice—that of Dr. Robertson—to excise the cicatrices. With the view of inducing anaesthesia, an attempt was made to administer chloroform; but the first inhalation threw the patient into so violent a spasm, that its use was desisted from, and Mr. White excised three out of the four cicatrices

without its aid. On account of the struggles of the patient, the fourth was not removed. On the 20th, the patient, who previously had been quiet, became excited and occasionally delirious. With the exception of short periods of sleep, he was incessantly talking. During the day, he expectorated a large quantity of mucus—at first clear and frothy, becoming tinged with blood as the night approached. For the first time, he complained of extreme thirst. His mouth and throat were parched and painful; yet he could not quench his thirst, as not only the attempt to drink, but even the sight of water, brought on severe convulsions. As night drew on, he became so furious that, assistance having been obtained from a neighbouring asylum, a strait-waistcoat was placed upon him. From twelve midnight, until 10 A.M., doses of one-third of a grain of extract of Calabar bean were hypodermically injected every two hours without in any way affecting the progress of the case, although the physiological effect of the drug upon the pupils was obtained. Between 12.35 and 2.35 P.M., three doses of half a grain each were subcutaneously administered with only negative results. At 2.55 P.M., two drachms of chloral, and again at 4.50 P.M., one drachm, were injected into the rectum with the primary effect of decidedly quieting the patient, and alleviating the spasmodic movements; but latterly, as above stated, his manner became so wild, that the imposition of restraint was rendered a necessity. Just before midnight of the 20th, we left the patient struggling, and displaying immense muscular power. At 1 A.M., on the 21st, his body began to relax in its efforts. His delirium was now not that of a maniac, but more like the low mutterings of the imbecile or the general paralytic patient. The respiration became short and gasping. At the wrist, the pulse was so feeble and so quick that it could not be counted. Feebly, now and then, the patient asked for air, saying he was being stifled with smoke. Gushes of "coffee-ground" matter were constantly being ejected from his mouth. Several times during the day, the face became perfectly livid from muscular spasm. From being plump and well nourished, the body in a few hours became shrunken and emaciated. To the hand it felt clammy and moist. At 5.55 P.M., the patient had an epileptiform fit of a few minutes' duration. From this time until his death, at 7 P.M., consciousness, which previously had at intervals been present, never returned. The therapeutics of the 21st, in so far as they had no appreciable effect upon the progress of the case, do not require much comment; yet, as illustrative of the extreme tolerance of poisonous drugs in this malady, I may mention that, during the last twenty hours of his life, the patient received subcutaneously seven grains of the extract of Calabar bean and ninety-two minims of dilute hydrocyanic acid; half a drachm of liquor ammoniæ fortior, much diluted, was also injected into one of the superficial veins of the leg.

At the *post mortem* examination, made a few hours after death, nothing beyond the usual appearances of death from asphyxia were observed. The cerebellum, part of the cerebrum, and the medulla oblongata were transmitted to Dr. Lockhart Clarke for inspection, by whom the duty, on account of illness, was delegated to Mr. Kesteven. That gentleman reports that, beyond intense congestion, nothing was discoverably wrong in the specimens.

**CASE II.**—A farmer's boy, aged 14, was admitted into hospital on the evening of May 4th, 1870, under the care of Dr. Ransom and Mr. Thompson. About three months previously, a dog belonging to his father had bitten him on the upper lip and bridge of the nose. Immediately after the receipt of the injury, lunar caustic was applied to the wounds. Until the evening of April 30th, the ordinary occupation of the patient was followed without discomfort; but on the evening specified he felt chilly, and on the morrow had an attack of nasal catarrh. During May 1st, when eating or drinking, slight muscular tremors were experienced. From this date until admission—three days afterwards—the progress of the case was slow, but unmistakable. On reception into hospital, the patient had a peculiarly frightened, anxious expression. The respiration was quick and gasping. Not only were spasms excited by attempting to eat and drink, but also by cold air impinging upon the surface of the body. To the hand, the skin felt cool. The pulse varied from 80 to 90 beats in the minute. Now and then the patient spat small quantities of clear and rather tenacious saliva. In the recital of his symptoms, the volubility of the patient was extreme; yet his answers to questions proved beyond dispute the possession of perfect mental power. At 10 P.M., one drachm of hydrate of chloral was injected into the rectum, and retained with the effect of warding off the spasms for four hours, unless when, at his own request, the patient drank thrice of milk. About midnight, in accordance with the suggestion of Mr. Thompson, mercurial ointment was freely rubbed into the inner surfaces of the thighs. From two o'clock in the morning of May 5th until midnight, the disease was modified by the timely administration of chloral hydrate. During the day, 200 grains of the drug were administered by the rectum in four doses, with the most satisfactory results.

\* Extracts from a paper read at the Midland Branch of the British Medical Association.

So much was the hyperæsthesia diminished, as to allow the patient to eat and drink small quantities of solids and liquors without suffering much inconvenience. For at least a third part of the day, the patient slept, whilst in the intervals there was entire freedom from pain. The pulse and respiration, however, increased in rapidity; but towards evening the patient, who previously had been quiet and tractable, became excited, and at times almost unmanageable. A considerable amount of difficulty seemed to be experienced by him in getting rid of the viscid mucus which filled his mouth and mechanically impeded his breathing. From 9.30 on the evening of May 5th, until 1.30 on the morning of May 6th, he slept. On awaking, at his own request he received and drank several spoonfuls of milk; but at five o'clock, without appreciable cause, most severe spasms rapidly followed each other, with the result of very soon exhausting the patient. His face, from being that of a well-conditioned lad of fourteen, became almost instantly transformed to the sunken, shrivelled visage of an old man. As death approached, the surface of the body became cold and moist; the respiration jerking, short, and slow; whilst at the wrist the pulse could not be counted. Until within a short period of his death, the patient was in full possession of his mental powers. Quietly, and without a struggle, he died at 11.15 A.M.

Five *post mortem* thermometrical observations were made *per rectum*, which proved, beyond a doubt, the intensity of the chemical change taking place in the body, at least during the latter stages of the malady. The temperatures were as follows:—11.30 A.M., 106.2; 12.45 P.M., 103.4; 1.45 P.M., 101.2; 2.45, 98.4; 3.45, 91.2.

At a necropsy made shortly after death, appearances similar to those noted in the case of Wadsworth were observed. Dr. Ransom examined the blood of the patient, but microscopically could detect no deviation from health.

CASE III.—A boy, aged 6, was admitted into hospital on the evening of September 20th, 1870, under the care of Dr. Robertson. Two months previously, he had been bitten by a neighbour's dog in several places. Directly after the receipt of the injury, tincture of opium, and afterwards lunar caustic, were applied to the wounds. The patient's health continued good until two days prior to admission, when he had a feverish attack. On the morrow he was sick, and complained of headache. During that day, his mother observed the sighing character of the respiration, which was intensified by any one approaching the bed on which he lay, or the mere handling of his bedclothes; but more especially by attempts to eat or drink. On admission, he was noted to be a healthy-looking and well-nourished boy, with an anxious, yet intelligent expression of face. Questions relative to his complaint were answered with a volubility beyond his years, yet sensibly. No pain was felt in the cicatrices of the bites, and no redness was observable. When a cup of water was offered him, with a peculiar grin upon his face, he convulsively seized it; but as soon as the cold vessel touched his lips, a spasm was induced. At first, the spasmodic action seemed confined to the muscles of respiration. Not only were they excited by attempts at drinking and eating, but also by the slightest motion in the room. The temperature in the axilla was 100.4. The pulse was regular and full—102 beats in the minute. Although pain in the throat and epigastrium was complained of, still there was but little thirst, and the tongue, though furred, was moist. At 7.35 P.M., and again at 9.30, extract of Calabar bean, to the extent of one-sixteenth and one-eighth of a grain, was injected into the rectum, with beef-tea and eggs, without alleviating the symptoms; on the contrary, the spasms became longer in duration and more severe, and the pulse from 102 rose to 150 in the minute at midnight. On the morning of the 21st, the patient, from being quiet and docile, became excited and irritable. He chattered constantly to his attendants of his complaint, or of whatever occurred at the moment. Respiration became jerking and hurried, and the pulse rapidly increased in frequency and fulness. Towards midday, for the first time, the patient spat a quantity of viscid saliva tinged with blood, and several times during the remainder of the day, he vomited large quantities of bilious fluid. At this stage, the urine was examined, but, beyond a deposit of lithates in cooling, nothing abnormal was chemically or microscopically detected. In the afternoon, delirium supervened, and he was seen by his father and mother, who received from him no sign of recognition. By the evening, the third or exhaustive stage had commenced. The patient lay comparatively quiet. The spasms, though frequent, were moderate in force. Respiration was embarrassed and quick, the effort producing a gurgling noise in the throat. From the corners of his mouth the saliva kept trickling. The conjunctivæ were deeply injected. At 3.15 P.M., an hour before death, the temperature in the axilla was 104, and the pulse 168. At 4.15, he died quietly. During the 21st, three grains and three-fourths of extract of Calabar bean, and one-eighth of a grain of acetate of morphia were administered without producing physiological or therapeutical effects.

It is but fair, however, to add, that part of the bean (which was injected into the rectum) was not retained; yet still, considering the age of the patient, the remainder should have been sufficient to at least cause contraction of the pupils.

A *post mortem* inspection revealed nothing beyond what was seen in the other cases.

## THERAPEUTIC RECORD.

VERATRUM VIRIDE AN ANTIDOTE TO OPIUM.—Dr. E. H. Sholl, of Alabama, communicates to the *Philadelphia Medical and Surgical Reporter* a case of poisoning by morphia, which was cured by veratrum. The patient, a negro boy, aged 15, had typhoid fever, and took an overdose of morphia, which had been prescribed for hiccup. It was followed by stertorous breathing, contracted pupils, etc. His mouth was held open, and eighteen drops of Norwood's tincture were poured in with two ounces of brandy. In one hour, every symptom of poison had vanished.

EXCISION OF CANCER OF THE OESOPHAGUS.—The last number of the *Archiv für Klinische Chirurgie* contains a paper by Dr. Billroth, in which he proposes, in cases of carcinomatous stricture of the oesophagus occurring in an accessible situation, to cut out, through its whole circumference, that portion of the tube which contains the disease. He has not yet performed this operation on the human subject; but he is led to believe in its practicability, first from the occasional restoration of the urethral canal after its division, and secondly by the result of an experiment which he performed on a dog. He cut out about an inch and a quarter of the animal's oesophagus, fastened the lower end to the edge of the wound by two sutures, and fed the dog with milk through an oesophageal tube passed through the mouth into the stomach. The sutures were removed about a week after the operation: there was considerable mucous discharge from the wound. The external wound gradually contracted, and the discharge diminished. About ten weeks after the operation, the external opening was completely closed. Bougies were frequently introduced so as to dilate the cicatrix; and the dog gradually gained the power of eating flesh, potatoes, etc., and swallowing them with ease. Three months after the operation, the animal was killed. The oesophagus presented a simple annular cicatrix, scarcely half a line wide: the tube was completely pervious.

CHLORAL.—Dr. J. B. Andrews of the New York State Lunatic Asylum states in the *American Journal of Insanity* for July that, since February 1870, chloral to the amount of 90 pounds had been used in treating 370 cases in the Asylum: 188, or about one half, being cases of mania. The average length of time of administration was 39 days in men, and 43 in women. In one case of melancholia, 20-grain doses were given for 257 nights, the medicine not losing its effect. In a case of mania, 60 grains were given for 195 nights in succession. He sums up its advantages as follows. It is a hypnotic which seldom fails to produce sleep, which usually lasts from four to eight hours. The sleep is natural, and one from which the patient can be easily aroused. It is more generally tolerated by the stomach than other sedatives. It does not constipate the bowels or disturb the secretions. It does not injuriously affect the appetite. It rarely produces headache, or leaves unpleasant effects. It does not lose its power by repetition, but the dose may often be reduced after the patient has become accustomed to its use, and seldom demands to be increased. When the necessity for its use has ceased, it often, for the first time, becomes disagreeable to the patient. Thus far we have met with no case where its administration has induced the habit of its use, which is one of the dangers of opium, cannabis Indica, etc. It allays muscular spasm and rigidity. No ill effects have been experienced from its use in cases of disease of the brain. We have observed no ill effects from its use in the reduction of the pulse or of the temperature. In cases of the opium habit, it has proved a valuable remedy to secure quiet and sleep, and allay nervous irritation until the system has rallied from the depressing influence of the former drug. In insanity, it is particularly useful to quiet restlessness and muscular activity. The strength of the patient is thus preserved, and time is gained for building up the general health by tonics and nutritious diets. Its ill effects we have observed are:—In some instances, it has induced nausea and vomiting. Unless largely diluted, it produces a burning sensation in the fauces and stomach. In many cases its influence is very rapid, the person falling asleep at once, which sometimes gives alarm to those unused to it. |

## BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 2ND, 1871.

## THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

SINCE the publication of our statement last week that His Royal Highness the Prince of Wales was suffering from a sharp attack of enteric or typhoid fever, the daily bulletins of his physicians have indicated very clearly and succinctly the progress of the malady, which has been in all respects regular in its manifestations; and, although deserving of the appellation which it received from the first as a sharp attack, the progress of the malady has been thus far favourable and free from complications. As all medical men are aware, the ordinary period of incubation of typhoid fever is from twelve to fourteen days. This is subject to variations and irregularities; but that is the accepted standard of the best authorities. Hence, when it was announced that, on the evening of the 14th ult., His Royal Highness first presented the signs which indicate the onset of the fever, the minds of medical men naturally reverted to the antecedent history of the patient at that interval of time. Enteric fever, it is known, is the result of the introduction of the miasm of decomposing animal matter, either in the form of aerial emanations such as sewer-gas, or of local pollution of the drinking-water by infiltration of such matters; and, whenever we meet with a case of enteric fever, we always look to the local circumstances under which the patient was placed at a date corresponding to that of the ordinary commencement of the period of incubation.

Thus, then, it was at once remarked that the date corresponded with that of the Prince's visit to Lord Londesborough at his seat at Scarborough. In connexion with this visit, certain medical circumstances were also reported on good authority. Thus, the party at Lord Londesborough's included their Royal Highnesses the Prince and Princess of Wales, with Colonel Ellis, the Countess of Macclesfield, Duke of Beaufort, Duchess of Manchester, Lady Cecilia Bingham, Lord Carington, the Earl of Chesterfield, and Mr. Baldwin. Nearly all, including especially Her Royal Highness the Princess, the Duke of Beaufort, Lady Cecilia Bingham, the Duchess of Manchester, Lady Londesborough, and Colonel Ellis, are known to have been suffering during the visit with symptoms of constitutional disturbance. These symptoms passed off rapidly, except in the instance of the Countess of Londesborough, who, it is stated, was much indisposed for ten days afterwards.

Four days after the date on which His Royal Highness the Prince of Wales sickened with enteric fever, Lord Chesterfield, who had been one of the party at Scarborough, was also attacked. Lord Chesterfield had been on a visit after leaving Scarborough, and was seized after reaching home at Bretby Park, Burton-on-Trent. These series of events taken together afforded, and still afford, a strong presumption in favour of the correctness of the local etiology which the best informed persons were disposed to assign as the probable explanation of the attack. But still further investigation develops some important facts which will weigh against this strong presumption. In the first place, Lord Londesborough states that the water-supply of his house is that of the town of Scarborough, and that it is pure and excellent. The sewers had been purposely examined and thoroughly flushed, and a turncock was kept on the premises during the visit for this purpose. Moreover—and this is the strongest fact in this group of considerations—four children have been staying in the house for some months, and have been, and still are, in excellent health. It has also been stated that there is no typhoid fever at Scarborough, and that Lord Chesterfield was not staying in the same house. There were, however, a few deaths from enteric

(typhoid) fever registered at Scarborough during the last quarter—nine deaths from fever in all, of which seven were from enteric fever; and two young children died of the same fever in the middle of this month. From want of space for the whole party, Lord Chesterfield slept in an adjoining house, but of course passed his time with the party, and joined them at meals. Little importance, therefore, attaches to either of these statements. But a very important circumstance, belonging to another order of events, is the fact that, since the Prince fell ill, one of the grooms at the Sandringham stables, who did not attend His Royal Highness to Scarborough, has sickened with the same disease. Moreover, at this moment it is known that typhoid fever is prevailing in many parts of England. We give in another column some details of its prevalence at this moment in London. Of course there will be no delay in instituting the fullest inquiry into every possible source of origin and contagion of fever both at Scarborough and at Sandringham.

The actual history of the two cases of typhoid—viz., of that of His Royal Highness and Lord Chesterfield—during the period which is usually that of incubation, appears to be as follows.

His Royal Highness the Prince returned to London on Saturday, November 4th, in good health, or at least without any appreciable disturbance. He went down to Sandringham on Monday morning. From this period till the following Monday, the 13th instant, there was nothing to remark until late in the afternoon of that day, when, on returning from shooting in the neighbourhood, he complained of chilliness, shivering, headache, and depression. On the following day, a whitlow appeared on the forefinger of his right hand. This was seen and attended to by Dr. John Lowe, of King's Lynn, the medical attendant of the household at Sandringham; it did not prevent His Royal Highness from carrying out his intention of going on a visit to Lord Carington at Gayhurst that afternoon. On Wednesday, the whitlow was more painful; and Mr. Oscar Clayton, Extra-Surgeon in Ordinary to His Royal Highness, was summoned from town, and remained in attendance on the Prince at Gayhurst until Friday, when the Prince returned to town. The whitlow, and one which had threatened on the other hand, were promptly cured. The Prince, on Friday, attended the French play. Meantime, however, with a view to the strengthening of his general health, and to meet the indications afforded by the local inflammation of the finger, a careful dietary and a suitable tonic treatment had been enjoined, and observed by His Royal Highness. He returned on Saturday to Sandringham, and was seen on Sunday by Dr. Lowe. On Monday, Dr. Lowe found that febrile symptoms were palpable; and, in the evening, Mr. Oscar Clayton was telegraphed for. Arriving on Tuesday morning, he found that the symptoms were now characteristic of typhoid fever, and announced this as the diagnosis. Sir William Jenner being at the moment in Scotland in attendance on Her Majesty, Mr. Clayton telegraphed to London for Dr. Gull. Her Majesty was at the same time informed of the nature of the Prince's illness. The symptoms developed according to the usual course of the disease at this stage; and on the afternoon of the next day, Wednesday, the 22nd November, Dr. Gull arrived from London, and coincided in the diagnosis and treatment. Sir William Jenner arrived on Thursday, and from this stage they jointly took charge of the case.

The course of the disease since that time has been portrayed in the bulletins. It has now reached its nineteenth day. Of course, in a fever such as typhoid, there is no question of critical days. It must run its course, which, as we intimated, is never, in a regularly marked case, less than twenty-one days; and, in a rather severe attack, such as this, it may extend for a term of twenty-eight days. Happy the patient in whom these symptoms take a favourable course, and whom his medical attendants are enabled to pronounce at this stage to be progressing favourably, and to be suffering from no collateral complications. Lord Chesterfield's attack was also

a severe one, apparently more so than that of His Royal Highness. It commenced four days after it. He has been attended by Dr. Evans of Birmingham, and at a time, when the symptoms had a serious aspect, Dr. Murchison was called in consultation from London. The preliminary symptoms resembled those of the Prince, and included the formation of a slight abscess. The patient is now progressing in all respects favourably. Of course, it will not be left out of consideration that the characteristic disturbance of health of the various members of the party at Scarborough, their subsequent dispersion, and the onset of enteric fever in two of its members, at different parts of England, within four days of each other, may belong to the chapter of surprising accidents. Typhoid fever is essentially local: it is a fever of the country as much as of the town; it is even the fever of the country; and it is especially an autumnal fever—the fall-fever of American writers. Here, then, are all the scattered elements for a remarkable coincidence.

It is usually, however, possible to trace out and to remove the causes of typhoid, and hence the importance of a complete investigation such as will now be set on foot. In view of this, we omit to refer to circumstances connected with the Scarborough house, having a bearing on this question, which have been communicated to us from local and other sources, and of which only such investigation can determine the relative importance.

We have every reason to hope to be able to speak in our next issue of the convalescence of the Prince, as having already satisfactorily set in.

#### OUR CONVICT SYSTEM.

THE blue-books issued by the several departments of the State are published annually, for the purpose of giving information on all subjects that have occurred in each department during the previous year. These volumes are justly considered to be public property, for they bring to light, officially, state matters and doings which otherwise would remain in comparative obscurity. The Directors of Convict Prisons of England have just issued their yearly volume on the discipline and management of these prisons for the year 1870.

The convict department under State control has, in consequence of the cessation of transportation, grown into an important service. The statistics of the prisons, published in the last volume of the *BRITISH MEDICAL JOURNAL*, gave proof of this; and the contents of the volume now before us give similar testimony. The medical department of this service has also, of necessity, increased in extent and importance. The following figures are quoted in support of these statements. The daily average number under sentence of penal servitude in the government prisons during the year 1870, was 9,131—men, 7,941; women, 1,190. The mean daily average for the ten years ending 1870, was—men, 6,337; women, 1,174.

We are forcibly convinced at the very outset of our examination of the convict health-returns given in this recent volume, of the necessity for keeping in mind that the sentence of penal servitude is never carried out in entirety in any one of the government prisons. Length of sentence undergone, health, physical condition, age, and even conduct, may, during any period of sentence, be the cause of transfer from any one of these prisons to another. This rule of the service is apparently invariable, and, without question, it is both beneficial and humane; but, in consequence of this rule, we unhesitatingly state that the yearly death-rate of any of the prisons is of no value at all as a test of the death-rate of penal servitude convicts. The individual prisons are, in fact, but sections of one system under the immediate control of the directors in Parliament Street; and reliable statistics of sickness and mortality during sentence, can only be obtained by embracing the total number under sentence without reference to location. Taking this view

of the question, we find 123 deaths from all causes during 1870, out of the daily average undergoing sentence—13.4 deaths per 1,000. The male death-rate was 12.5, or of natural deaths only (excluding six accidents on public works and two suicides) 11.5 per 1,000. The female death-rate was 19.3. The mean mortality for the ten years 1861-70, was per 1,000—men, 13.8; women, 13.7.

Phthisis was the cause of death in 41 men and 10 women. The deaths from this disease per 1,000 of the daily average were—men, 5.1; women, 8.4; and the percentage of deaths on the total number of deaths—men, 41; women, 43.4. Other diseases of the respiratory organs were fatal at the rate of 2.2 per 1,000, and 18 per cent. of the total male deaths. Diseases of the brain and nervous system ended fatally in 9 men and 4 women; and diseases of the heart and great vessels, in 5 men and 1 woman. No death occurred from fever. One man, aged 21, died at Chatham of pyæmia, eight days after a severe accident. Two men who met with accidents on the public works, died at Portland of "mortification" after amputation. In one of these cases, "mortification of the left arm" followed amputation of the thumb; and in the other, mortification of the leg after amputation of the foot. The medical reports are anything but clear on the nature and termination of accidents at the public works' prisons; and the recorded results of operations performed at those prisons are also confusing and obscure.

The total daily average number for the year of sick under treatment in the various prison hospitals was—men, 493.9, or 62.1 per 1,000; women, 61.9, or 52.01 per 1,000.

The number of insane cases in the year is doubtful. The returns on this head are confused and puzzling. Several prisoners were evidently insane when first received; others, about 27, became insane during the year; 13 were removed to lunatic asylums; and 29 or 30 were remaining on the last day of the year. The cases that occurred during sentence were at the rate of 3.2 per 1,000. Millbank prison receives nearly all the insane prisoners from the other government prisons. The remarks of the medical officer of this prison on the insanity of these convicts are of importance. They give undoubted testimony that the cases of insanity which come under treatment every year in the convict prisons are mostly consequent on previous criminal life, and not on prison discipline.

The limits of this article will not admit further detail of the health returns of these prisoners. We cannot, however, close without mentioning some evident defects in the mode of rendering the medical reports of these prisons. We are fully aware that the occupants or these establishments are under punishment, and that scientific medicine must, therefore, give place to the demands of the law; the health of the prisoner is to be cared for, but the sentence must also be carried out in its integrity and rigour. Granting all this, we nevertheless state that the eleven detached and disconnected medical reports cannot fully represent the sanitary condition of the prisons; nor can they render that favourable testimony to the system of management which they could and ought to do. A medical report is wanted which would embrace the whole of the prisons—which would tell of the sickness and mortality of prisoners who began their sentence in good health, and of the effect of imprisonment on convicts who were in bad health when sentenced. We look in vain through this yearly volume for this information. The tables of deaths which accompany the medical reports show that very many of the deaths were from diseases which began before the commencement of the sentence. This was the case in the majority of the women who died: and other parts of these reports give abundant testimony of the previous unhealthy condition of many of the convicts. The death-rates, even in their present undistinguishing form, speak well for the general management of these prisons; but we are confident that a larger amount of credit would accrue to the responsible officers of this service by making these medical returns more comprehensive and

general, and by showing how far the death-rates are influenced by diseases which began previously to imprisonment. We therefore commend these remarks to their consideration.

It is proposed to establish an asylum for idiots in Derbyshire.

SIR RODERICK I. MURCHISON, Bart., has bequeathed £1000 to Dr. H. Bence Jones, his physician.

DR. CHADWICK AND DR. HEATON of Leeds have been appointed Justices of the Peace for the West Riding of Yorkshire.

NEARLY £2,000 has been received for the building fund, and about £3,000 towards the endowment of the proposed Infirmary at Louth.

DR. THOROWGOOD has been elected Lecturer on *Materia Medica* at the Middlesex Hospital Medical College; and Mr. Henry Morris joint Lecturer, with Dr. Liveing, on *Anatomy*.

THE foundation-stone of the extension works of the Queen's Hospital, Birmingham, is to be laid on Monday, the 4th of December, by Lord Leigh, Lord Lieutenant of Warwickshire, and Provincial Grand Master, with Masonic honours and great ceremony.

SMALL-POX is epidemic in Buda-Pesth. At the meeting of the Medical Society of the place on November 18th, a committee was appointed to watch the progress of the disease and make weekly returns thereon.

A MEETING of the Medico-Psychological Association will be held at the rooms of the Medical Society of London, 32A, George Street, Hanover Square, on Wednesday, December 6, at 8 P.M. The President, Dr. Maudsley, will read a paper on the question, "Is Insanity on the increase?"

DR. GILBERT CHILD, of Oxford, strongly recommends for English villages and small country towns the Milanese system of the drainage of houses into water-tight cesspools, emptied frequently, efficiently, and quite inoffensively, by means of a hose and a barrel-cart previously exhausted of air.

#### THE MEDICAL PROFESSION IN ROUMANIA.

IN 1864, of 206 doctors of medicine in Roumania, 135 had German diplomas. A school of medicine was then formed at Bukarest; and since then, of 133 doctors of medicine, 37 only have taken their degrees in foreign universities. The majority have studied at home, visiting the French schools for a limited time only. The number of German practitioners settling in Roumania is likely to be further limited by a new regulation, which compels foreigners to undergo an examination carried on in the Roumanian language.

#### THE CHARITY ORGANISATION SOCIETY.

THE Medical Committee of the Charity Organisation Society will assemble at the office of the Society, 15, Burlington Street, Adelphi, on Saturday (to-day), December 2nd, at 4 P.M.; and they will be glad to meet any gentlemen, being medical officers or working governors of free dispensaries, who are willing to consider the desirability of converting their institutions into provident dispensaries. The Charity Organisation Society has issued invitations for a conference to be held at the house of the Society of Arts, John Street, Adelphi, on Tuesday, December 12th, at 3 P.M., to consider the best methods of checking the abuses now incidental to out-patient hospital relief, with special reference to the expediency of extending the provident principle. The chair will be taken by W. H. Smith, Esq., M.P.; and we understand that Mr. Stansfeld and many other influential gentlemen, both medical and lay, have promised to attend. The object of the conference is to discuss the province of the Poor-law, the Dispensary, and the Hospital, with reference to the sick poor; and to promote concerted and harmonious action among these agencies.

#### THE STRASBURG MEDICAL SCHOOL.

IT is reported that the French government intends to establish two schools, one at Lyons and the other at Nancy, in place of the Strasburg medical school. The Strasburg professors are to go to Lyons; and it is expected that the school will assume an important position in consequence of the large amount of hospital accommodation in that city. At Nancy, physics, chemistry, and physiology will be more especially taught.

#### HOSPITAL SUNDAY IN RICHMOND.

HOSPITAL Sunday was kept for the third time in Richmond and the neighbouring parishes on Sunday, November 19th, when, we are glad to report, the sum of £222 : 12 : 7 was added to the annual funds of the Richmond Infirmary, as the result of the earnest appeals made in its behalf in the parishes of Richmond, Twickenham, Ham, Kew, Petersham, and Mortlake. At the last meeting of the Committee, the sum of £2000 was handed over to the Treasurer, being an immediate legacy from the late Mr. George Wall of Richmond. A further sum of between £4000 and £5000 will be payable at a future period. At the beginning of the new year, six additional beds will be provided, of which four will be children's cots, making a total in all of twenty-one beds.

#### THE MURPHY ANNUITY FUND.

THE funds subscribed and promised by the profession towards the purchase of this annuity have already amounted to a sum sufficient to secure for Dr. Murphy a life-annuity of fifty pounds. Some inevitable delay in obtaining the necessary age certificates, etc., has prevented the treasurer (Dr. Arthur Farre) from purchasing the annuity. The papers, however, will be ready, and the amount purchased, on January 5th, 1872. In the meantime, the amount subscribed being in excess of that which is necessary to purchase an annuity on the sole life of Dr. Murphy, and many of the friends of Dr. Murphy being desirous to include in the provision his wife, who would otherwise be left destitute at his death, it is intended that an effort shall be made to increase the existing surplus to a sum sufficient to extend the proposal over the two lives. For this purpose £130 will be wanted, and it must be collected before the close of the year. Mr. Campbell de Morgan, 51, Upper Seymour Street, will act as treasurer of the supplementary fund, and Dr. Wiltshire, 57, Wimpole Street, W., as honorary secretary. When the full amount is collected it will be handed over to Dr. Farre, the treasurer of the original fund, who will invest the whole sum in the names of the trustees originally announced.

#### JENNER MEMORIAL.

THE following circular has been issued, dated November 25th, 1871, 96, Eaton Place, London, S.W., and signed by Colonel Kingscote, M.P.

"May I request your kind consideration of the following statements? The late Dr. Edward Jenner was born, lived, and died at Berkeley in Gloucestershire. The church has lately been restored, and it is desired to fill the east window with stained glass to his memory. The church is a noble edifice, and the window is well adapted for a most beautiful design, which has been furnished, representing our Lord in His various acts of healing, taken from the Gospel of St. Luke—'the Beloved Physician.' The estimated cost of this design is £500. It may be well to state that vaccination was discovered by Jenner in 1798, and became general in England in 1799, and throughout all Europe before 1816. The important 'Vaccination Act' passed in 1840, and was made compulsory in 1853. Honours and rewards were conferred on Jenner as a public benefactor. The Emperor Napoleon valued his services to mankind so highly that he liberated Dr. Wickham, when a prisoner of war, at Jenner's request, and, subsequently, whole families of English, making it a point to refuse nothing that he asked. When the allied potentates visited England in 1814, the Emperor of Russia sought an interview with Jenner, and offered to bestow on him a Russian order of nobility. France has erected a statue in honour of him; and, in 1858, a statue was erected to his memory, in the presence of the late Prince Consort, in Trafalgar Square; which, however, has been since removed, and placed in Kensington Gardens, in a spot but little known, and can only be visited by pedestrians. May we not then, hope, that

this further testimonial of a memorial window may be deemed worthy to commemorate his services in the place where this wonderful discovery of vaccination dawned upon him, which occupied eighteen years of his life before he was able to give the benefit of it to the world? In London, in 1723, one out of fourteen deaths was caused by small-pox. In France, in 1734, the ratio was one in ten. This dire disease has been, and still is, raging amongst us; but a gracious Providence has provided, through the instrumentality of this great man, a remedy; and it seems fitting that some further work of art should be erected to commemorate so world-wide a blessing at the place of his birth and death. All contributions, however small, may be paid to the Bankers or Secretary."

Every such movement must receive our cordial support. But we cannot but think that the compliment should be paid to, and not by, the medical profession of this country, and that the funds should be supplied by the general public, on whom Jenner has conferred such inestimable benefits.

#### THE LONDON COLLEGE OF PHYSICIANS.

WE are happy to learn that the College has now extended to its Licentiates a privilege which we have before craved on their behalf, but was until very lately limited to its Fellows and Members—namely, the use of the Library and Reading Rooms. This will now be as much open to their use as that of the College of Surgeons is to its members. With a view to the general comfort of all who may avail themselves of this privilege, the Reading Room has been redecorated, and, for the most part, newly furnished; the daily papers are provided, as also the quarterly, monthly, and other periodicals; besides which, a large number of carefully selected recent works on medicine, surgery, midwifery, and the collateral sciences, will be found on the tables for perusal, and the volumes will be replaced by others every three months, or oftener, as the Library Committee consider desirable. The Reading Room is open under the following regulations.

"The Reading Room at the College, for the convenience of Fellows, Members, and Licentiates, using the Library, shall be open daily—Sundays, and such other times as the Library Committee shall direct, excepted—from one o'clock until four o'clock from the 1st of October to the 1st of March, and from one o'clock until six o'clock from the 1st of March to the 1st of September."

This step is in every way creditable to the authorities of the College, and will, we feel sure, be highly satisfactory to all who have the honour of belonging to it, whether as Fellows, Members, or Licentiates. It is one further step towards the practical recognition of unity of medicine, and the equal rights of all who belong to the corporate bodies.

#### SCURVY IN BRITISH SHIPS.

A VESSEL arrived at Queenstown on November 13th with a large number of cases of scurvy on board. Dr. Scott, Medical Officer at Queenstown to the Emigration Commissioners, was requested to visit them; and he states that all hands except the captain were suffering from scurvy in a greater or less degree. He records, as a remarkable fact, that the chief and second officers, as well as the carpenter and steward, all of whom lived "aft", were very severely affected. The vessel had brought home a cargo of silver ore and logwood from Altata in California; and the passage from that port to Queenstown occupied but a hundred and twenty-seven days. Dr. Scott remarks that, having had considerable experience of scurvy, he has observed that all cases of the disease have occurred with guano, corn, or sugar cargoes; and hence he infers that some glaring errors in quantity or quality of diet, or some positive neglect with reference to antiscorbutics, must have been the direct cause of this severe outbreak of scurvy. We are informed, however, that Mr. Harry Leach has been directed by the Marine Department of the Board of Trade to institute an official investigation into the matter. It is proper, in the interests of science as well as of commerce, that the results of these official inquiries should be made known to the public. The Board of Trade causes to be published, with almost painful accuracy, the details of all inquiries ordered by them that relate to railway accidents and marine collisions; but regular reports having reference to health of crews seldom or never

find their way into general or medical journals; and, as a consequence, no positive opinion can be formed as to the benefit that has resulted from the operation of the Duke of Richmond's Act or of any measures adopted to improve the sanitary condition of our sailors at sea.

#### PREVALENCE OF TYPHOID FEVER IN LONDON.

ENTERIC fever, always more or less present in London, and especially prevalent at this season of the year, is just now abundant and of a severe type. During the last five weeks, the weekly deaths registered have ranged as follows: 27, 27, 32, 36, and 23, against 28, 22, 19, 20, and 24, for the corresponding weeks of last year. The number of admissions at the London Fever Hospital, Liverpool Road, has been reduced during the last few weeks by the opening of the Metropolitan Asylum at Homerton for fever-cases. Dr. Collie, the Resident Medical Superintendent at this Asylum, informs us that the present endemic condition may be considered severe. He writes: "Of enteric cases we have admitted fifty cases of true enteric fever; of these, twenty-nine were of a mild character, and twenty-six were severe, having been complicated with more or less of bronchitis, pleurisy, or pneumonia. Of the total admissions, we have had nine deaths. The causes of death were as follows: 1. Enteric fever: hæmorrhage. 2. Enteric fever: bronchitis. 3. Enteric fever: pleuro-pneumonia. 4. Enteric fever: bronchitis; hæmorrhage. 5. Enteric fever: bronchitis. 6. Enteric fever: hæmorrhage. 7. Enteric fever: bronchitis. 8. Enteric fever: pleuro-pneumonia; hæmorrhage. 9. Enteric fever: bronchitis; perforation; peritonitis. There remain at present forty-five enteric patients."

#### NEW POSTAL REGULATION.

THE Postmaster-General has, we are rejoiced to hear, resolved to free the public from that last avenue of offence by which the worst class of quacks have been wont to attack them. The handbills and museums which once discredited our streets have been pretty effectually cleared away by the action of the police under Lord Campbell's Act (with one exception, to which we propose shortly to call attention); but the broadcast circulation of the same class of circulars and books by post has continued on a larger scale than ever, and has been a frequent cause of offence and complaint. We are glad to learn that the Postmaster-General has issued an instruction stating that they are henceforth to be considered as coming under the ban of No. 14 of the General Regulations, and that their transmission will henceforth be arrested. The more respectable class of newspapers have of late years closed their columns to obscene advertisements of this class. We regret to say that there still remain some important provincial exceptions.

#### TRAFFIC IN HOSPITAL LETTERS.

AN extensive and systematic traffic in lying-in hospital letters, information about which should be made as public as possible, seems to be going on in the metropolis. It appears that Mr. J. W. Langmore, Resident Obstetric Assistant at the Middlesex Hospital—an institution which undertakes one of the largest lying-in practices in London—has discovered that a number of persons are in the habit of soliciting letters from subscribers of the Middlesex and the other hospitals of London. These are given freely by some of the governors, and without due inquiry as to the name, the address, or the fitness, of the applicants. The letter, thus obtained, is presented at the hospital supplying it; and the name, address, and other particulars of the patient, are entered, the patient at the same time receiving an order for attendance in confinement by a student of the hospital or by one of the nurses employed by the institution. The market value of one of these orders appears at present to be about two shillings; the price, like that of other commodities, fluctuating somewhat according to the supply and demand. If a bargain have been struck previously to the presentation of the letter at the hospital and the procuring of the order, the name and address of the buyer are of course given; but, should this not have been completed, the matter is easily arranged by the intimation of a change of address to the student or nurse. Not only is an extensive fraud of this

character now going on, we believe, throughout London, but it appears that a custom obtains amongst a certain number of the poor to procure a letter for as many charities as possible, to insure certainty of attendance when the confinement comes off. But, as it happens that several of the nurses are frequently employed by different charities, it also occasionally occurs that the patient is referred by these to one and the same nurse. Two cases have been brought under our notice, in one of which six letters from different charities were sent in by a nurse for attending one patient. In the other case, four letters were sent in; and in both instances the nurse succeeded in procuring payment from each institution. It has been always understood that the sale of other than lying-in letters has been carried on to a certain extent for many years; but, considering the facility with which ordinary out-patient relief is now obtained, the trade is not so flourishing as in former years. Although arrangements may be made by the authorities of the various charities to check to a certain extent this fraudulent traffic, the abuse will, we fear, always exist to a certain extent. The subject is one which deserves the attention of all hospitals and lying-in charities.

#### THE CHIEF EPIDEMICS OF THE LAST THREE YEARS.

INSPECTOR-GENERAL ROBERT LAWSON, President of the Epidemiological Society of London, delivered an address on this subject at the opening meeting of the Society. He indicated the necessity of a close observation, not of one but of every epidemic, over the greatest possible surface, and for a series of years, to afford trustworthy data for the determination of the general laws which govern the progress of this class of diseases in their diffusion over the earth; and illustrated the value of such inquiries by the ascertained facts with regard to small-pox, scarlatina, diphtheria, fever, and cholera, not only in this country but on the continent and in America. An example from the last two diseases may be given. In 1868 there was much fever in Asia Minor and along the shores of the Mediterranean as far as Spain; and in 1869 the disease, in various forms, was very prevalent through Europe from Madrid to St. Petersburg, while it remained very active at several points along the north coast of the Mediterranean. Fever increased in Berlin in 1870, and in Vienna a rather severe epidemic of typhus commenced at the end of that year and continued during the first half of 1871. It will be remembered that in 1869 malignant cholera made its appearance at Kiew, in Russia, in the summer of 1869, and towards the end of the year spread to some extent through the basin of the Dnieper; it, however, acquired no great force until 1870, when it involved the whole country from the Black Sea to St. Petersburg, but was not met with in Europe as an epidemic west of Russia. In 1871, cholera continued at St. Petersburg and extended to Archangel, to Helsingfors north of the gulf of Finland, and along the country to the south of that and the Baltic as far as Hamburg and Altona. There had been a severe outbreak in Persia, to the south and east of the Caspian, in the autumn of 1868, which continued into 1869; and in the course of that year this was to have been expected in Southern Russia or the corresponding latitude in Asia: it actually appeared at Kiew, 300 miles from the nearest sea, and 1500 from the nearest point where the disease was known to exist at the time, while every attempt to trace its origin to importation failed. It has been found, from an extensive examination of facts, that cholera as an epidemic will not penetrate a district occupied by an epidemic of fever (enteric excepted) until that subside, when its place may be taken by the other. The fever in Asia Minor in 1868, and in Europe in 1869, 1870, and 1871, seems to have limited the progress of cholera westward in these years, until it crept along the south shore of the Baltic a few months ago. It is worthy of observation that the relative distribution of cholera and fever during the first approach of the former to Western Europe in 1828, 1829, 1830, and 1831, presents year by year an almost exact parallel to that in the corresponding period, 1868, 1869, 1870, and 1871. In 1831 a fresh wave came from the south, which affected Smyrna and Constantinople, and extended into Hungary, and was experienced in this country in 1832. In 1871

a similar wave appeared in Southern Russia, and has been felt at Smyrna and Constantinople, and has given slight indications at Vienna; it remains to be seen whether the parallel will be completed by its becoming epidemic in this country in 1872.

#### TYPHOID FEVER IN LINCOLN.

AN example of official obstinacy or procrastination, we cannot say which, is reported from Lincoln, which has resulted, it is alleged, in disastrous consequences to a household in that town. It appears that the water of a pump close to the minster was examined by the Local Board, and reported to be unfit for drinking purposes. But, for some inexplicable reason, or rather stupidity, no means were taken to prevent its being used. As a consequence, it is said, typhoid fever seized a family who had just taken up their residence in a neighbouring house: one of the servants has since died of the attack. There seems to be good reason to believe that the water-supply was the origin of the mischief, as the members of the family were in excellent health previously to their drinking the pump-water. The papers do not state whether other families used the obnoxious water, or whether typhoid fever had been limited to the one household in question. The matter, in any case, demands the immediate attention of the authorities.

#### AUSTRALIAN MEAT.

WE observe several strikes on the part of inmates of workhouses against Australian canned meat. We have taken so active a part in favouring the introduction of meat from this source of supply, that we shall not be supposed to incline towards an unreasonable prejudice if we recall to mind that Dr. Gordon, the British Medical Commissioner during the siege of Paris, observed and explicitly stated, in a communication which he published in our columns, that while preserved meats afforded an excellent and nutritious variety of diet, they were not found to be fitted to preserve health if used as the sole substitute for fresh meat.

#### THE TREATMENT OF DISEASE WITHOUT ALCOHOL.

DR. COLLENETTE (Guernsey), speaking at a recent meeting of the National Temperance League, stated that, at a small hospital to which he is attached, from 1839 to 1853, both years included, the sum of £2,026 was spent for intoxicating drinks, or an average of £135 a year; with an average of thirty-one deaths. In the fifteen years commencing with the year 1854, there was spent only £212, instead of £2,026, or an average of £14 a year instead of £135, and with an average of only twenty-three deaths instead of thirty-one. His colleagues and himself had a perfect right, if they thought fit, to order any stimulant they pleased, and to any amount. His colleagues were not teetotalers; but to do them justice, he must say that the £14 of which he had spoken likewise included the cost of the drink consumed at the tables of the governor and matron's houses, and also in the porter's lodge; so that it would be seen that the patients had very little indeed. Speaking of the treatment of delirium tremens, he added:—With the facilities for drinking and getting drunk cheaply in Guernsey, you will not be surprised to hear that we have large numbers of delirium tremens cases. I do not know that the treatment of delirium tremens at the present day is so bad as it was when I was a pupil and first commenced, but I know that the general prescription is brandy, brandy, brandy—brandy and eggs, brandy and beef-tea, brandy and milk, brandy and ammonia, opium and brandy. I have treated delirium tremens for more than thirty years—and I have had some hundreds of cases—and I have treated everyone of them without a single drop of intoxicating drinks, and with the best results. I have scarcely lost a case of delirium tremens; but for thirty years not one has had a thimbleful of intoxicating drink. As to operations, he said:—In thirty years I have had to perform many operations, because in Guernsey we act the surgeon as well as the physician; and during those thirty years I have never, except in two cases, prescribed or let my patients have one single drop of intoxicating drinks; and these two cases to which I allude were

exceptionally treated in consequence of consultations, against my wish, against my own convictions, and against my own conscience. Both these cases terminated fatally, and are the only two cases that I ever lost after operation. Dr. Eastwood, of Darlington, recently brought forward in the JOURNAL facts to support the statement that the intemperate are particularly susceptible to the cholera-poison. We may observe, however, that the evidence of Indian observers does not always confirm this statement. Dr. Collenette states that, in the visitation of cholera in 1849, a very large proportion of the then drunkards of Guernsey were swept away. Many respectable and moderate drinkers likewise became its victims; but the teetotalers to a man were spared. Not one teetotaler in Guernsey, he says, died of cholera, and only two were attacked by the disease in a mild form. He treats all forms of diseases without the administration of alcohol, and believes himself to have been very successful during thirty years' practice.

#### MR. DURHAM'S PAPER ON THYROTOMY.

WE have received, from Dr. Morell Mackenzie, a reply to the observations by Mr. Durham on laryngotomy at a recent meeting of the Royal Medical and Chirurgical Society. It is of so great length that we can only state its purport; which is, briefly, as follows. I. He does not object to thyrotomy *in toto*, and has so stated in his writings; but he considers that an extralaryngeal method of extracting growths ought never to be adopted, unless there be danger to life from suffocation or dyspnoea.—II. In respect to the danger to life in thyrotomy, he had been careful to point out which cases were cancerous in published text. Making all allowance for disputed cases, there is a mortality of nine per cent.; and, taking into account Mr. Durham's five new cases, a mortality of seven per cent. In extraction of growths *per vias naturales*, there has not been any mortality.—III. The voice was recovered in 19 out of 37 cases of thyrotomy, or in 50 per cent., but in 75 per cent. of 93 published glottal extractions.—IV. It is not clear that more complete extirpation can be effected by the former than by the latter proceeding. Of 27 non-malignant cases, one was totally, and two were partially, failures: death occurred quickly in four. Of the remaining 20 cases, recurrence occurred in three, or in 15 per cent. In the 93 cases of laryngoscopic operation, recurrence took place only in six cases of complete extirpation; it also occurred in three other cases where there was partial failure.—V. Extraction by the fauces with the aid of the laryngoscope no doubt requires a certain practice and expertness; if it be more successful and less dangerous to life, such a consideration is by no means an argument for rejecting it.—VI. The operation for removal of laryngeal growths through the glottis is almost painless and bloodless, and does not oblige the patient to abstain from his pursuits for a single day. The same cannot be said of the incision of the throat and larynx; besides pain, risk, etc., it confines the patient for three to four weeks at least. Dr. Mackenzie explains and regrets the omission to tabulate a case of Mr. Durham's in *Guy's Hospital Reports*, series 3, vol. xii.

#### CROTON-CHLORAL-HYDRATE.

AT the recent meeting of German Naturalists and Physicians, Dr. O. Liebreich, to whom medicine is indebted for the introduction of chloral, called attention to the properties of a narcotic agent termed "croton-chloral-hydrate." It is made by passing chlorine into allyl; and is decomposed by alkalis into dichloride of allyl and formic acid, hydrochloric acid being also formed. The first effect of its administration to animals is marked anaesthesia of the head, while sensation is preserved over the rest of the body. Next, there is a general loss of reflex irritability; the pulse and respiration remaining unchanged. If a large dose be given, death is produced by paralysis of the medulla oblongata. The animal may be preserved alive by artificial respiration, the action of the heart remaining unaltered; whereas the final effect of chloral is to produce paralysis of the heart. That death arises from paralysis of the medulla oblongata in animals poisoned by croton-chloral-hydrate, is

shown by the fact that contraction of the diaphragm is not produced by galvanism of the central end of the vagus, whereas it follows irritation of the phrenic nerve. When the animal has so far recovered that the breathing has become natural, then irritation of the central end of the vagus produces contraction of the diaphragm. The effects of this agent had also been tried on the human subject in the Berlin Hospital. In a child to which it was given, complete anaesthesia of the parts supplied by the trigeminus nerve was produced, while the reflex irritability of the rest of the body was retained. The pulse and respiration were unchanged in number throughout. Further researches on insane patients gave the same result; and Dr. Liebreich concluded therefrom that croton-chloral-hydrate has the property of inducing profound narcosis of the brain without interfering with the other organs; while a correspondingly deep narcosis produced by chloral is accompanied by general anaesthesia and by dangerous lowering of the heart's action.

#### PROFESSOR HUXLEY AND MRS. GARRETT-ANDERSON ON VENTILATION.

MRS. GARRETT-ANDERSON, M.D., in moving at the School Board for a Select Committee on the Sanitary Arrangements of the School, said that she wanted from 800 to 1000 cubic feet of air-space to each child. Her object is excellent, but her requirements are exaggerated. Professor Huxley said that with such requirements the school-rooms must be ninety feet high, which shows that, great authority that he is in most physiological questions, he has not studied this one very carefully. Height above twelve to sixteen feet cannot be taken into consideration in estimating cubic air-space for ventilating a room.

#### BONE-SETTING IN ALGERIA.

IRREGULAR bone-setting has received more than usual attention in this country since the publication by Dr. Wharton Hood of the practice of Hutton, the famous London bone-setter; and on the Continent since Regina Dal Cin, an account of whose doings we gave in last week's JOURNAL, presented herself as a professional bone-setter in Italy and Austria. In connexion with the subject, the following extract from Cateron's *Travels in Algeria* will be of interest.

"On our return, I called upon the Schiek, Lisaid-Mansor. I found him stretched on a couch built of stonework cemented with clay, covered only with a few rags, and with a stone for a pillow. His leg, surrounded with bandages and herbs, was firmly tied up in, and kept straight by, a thick slip of bark. His foot was immovably fixed to a stake stuck in the ground. He is obliged to remain in this condition until the bones are united. This severe treatment is not unfrequently fatal; but, if the Arab has a good condition, and gangrene does not set in, he recovers with a limb more or less straight. The poor Schiek was busy flipping off, with a handkerchief tied to a stick, the swarms of flies which were attracted to his wound. At the foot of the couch was the Tebib or surgeon, himself reciting incantations and prayers over the broken limb. He appeared much put out by my entrance, for the Arabs think that all Europeans understand medicine; but he was reassured when he saw that I merely looked on without interfering. I offered the patient a few expressions of sympathy, and hastened away, for the room smelt horribly close and offensive."

#### A SUGGESTION TO THE LOCAL GOVERNMENT BOARD.

FROM the character of the observations made by the stipendiary and other magistrates when administering the provisions of the vaccination law, they would seem to be so imperfectly acquainted with the important facts demonstrating the prophylactic value and constitutional innocence of the proceeding, that we venture to suggest to the chief of the Medical Department of the Local Government Board that it will be highly advisable to furnish them with a memorandum, which might convey the facts upon which that law is based, and which might occasionally afford a text when they desire to reply to the sophisms of the antivaccinators prosecuted before them. It is much better that these persons should be convinced than convicted. The police-reports, now often published, are so worded as to create an impression of injustice and oppression, and rather to kindle than to repress further agitation.

## BILLROTH ON OVARIOTOMY.

IN an interesting series of "Surgical Reminiscences" which he is publishing in the *Wiener Medizin. Wochenschrift*, Professor Billroth describes nine cases of ovariectomy which he has performed, and of which seven have been successful. He notices the greater frequency of the operation in England than on the Continent, and remarks that, with such results before them as have been gained by Spencer Wells, surgeons must give up the idea that ovariectomy is one of the most fatal of operations; for, in a judiciously planned and skilfully performed operation of the kind, recovery is the rule, and death the rare exception. To arrive at this result, however, the rules laid down by the English surgeons must be carried out to the letter. He had, he says, the good fortune of witnessing two of Spencer Wells's operations, and of receiving much valuable instruction from him; and he remarks that he will be quite content if in the course of his life he shall be able to save by ovariectomy only half as many human lives as the English surgeon, whose disciple he will always consider himself, has done.

## INFLUENCE OF MARRIAGE ON THE DURATION OF LIFE.

M. BERTILLON lately read before the Academy of Medicine a paper on the relative influence of marriage and celibacy, based on statistical returns derived from France, Belgium, and Holland. In France, taking the ten years 1857-66, he found that, in 1000 persons aged from 25 to 30, 4 deaths occurred in the married, 10.4 in the unmarried, and 22 in widowers; in females at the same age, the mortality among the married and unmarried was the same—9 per 1000, while in widows it was 17. In persons aged from 30 to 35, the mortality among men was, for the married, 11 per 1000, for the unmarried, 5, and for widowers, 19 per 1000; among women, for the married, 5, for the unmarried, 10, and for widows, 15 per 1000. There appears to be a general agreement of these results of marriage in Belgium and Holland, as well as in France and Paris.

## SCOTLAND.

THE following gentlemen have been elected presidents of the Royal Medical Society of Edinburgh for the current year:—E. Willis Way, M.B.; Lewis Shapter, B.A.; Henry C. Martin, M.B.; and Arthur J. M. Bentley, M.B.

THE following office-bearers of the Edinburgh Obstetrical Society were elected on November 22nd:—*President*: L. R. Thomson, M.D. *Vice-Presidents*: A. R. Simpson, M.D.; J. Matthews Duncan, M.D. *Treasurer*: James Young, M.D. *Secretaries*: R. P. Ritchie, M.D.; J. Andrew, M.D. *Council*: A. Keiller, M.D.; G. S. Smith, Esq., and T. H. Pattison, M.D.

## ST. ANDREW'S UNIVERSITY.

MR. RUSKIN has been elected Lord Rector of the University of St. Andrews. Mr. Ruskin holds a professorship in the University of Oxford, which, by the Universities Act, prevents his accepting the honour, unless, as it is said, he be only a "Professor Extraordinary" in that University.

## IRELAND.

## SMALL-POX IN DUBLIN.

SMALL-POX is still on the increase in Dublin, though the deaths are not numerous. The number of persons attacked, and the spread of the disease, is very universal. It is the invariable rule that those who had been previously vaccinated have the disease in a very modified form. Revaccination is also on the increase. The present outbreak of small-pox in Ireland will go a long way towards stamping out the absurd prejudice against both vaccination and revaccination. The Poor-law Commissioners have issued a form for the return of small-pox cases in the Dublin unions, which, no doubt, will afford very useful information in

the next Annual Report. It is a pity, however, that it contains no column for the statement as to the previous vaccination of patients: it would be of the utmost importance that such information should be given in all cases, as well as the relation between the existence of well-marked vaccination-cicatrices and the modification of the disease.

## CHARGE AGAINST A DISPENSARY MEDICAL OFFICER.

MR. MAURICE SPOTSWOOD, Medical Officer of the Cahirciveen Dispensary District and Workhouse, retains his appointments, the Poor-law Commissioners having, at the request of the Guardians (as mentioned in our last), withdrawn their order that he should resign. The news was celebrated by blazing tar-barrels and other marks of popular rejoicing.

## THE NECROPSY OF TALBOT.

WE understand that Talbot before his death gave specific directions that, at the *post mortem* examination of his body, only his head and neck were to be examined. This, and the fact that the sole object of the necropsy by the surgeons was to discover the immediate cause of death, explain the circumstance that the bullet was not at the time searched for. We understand that the unanimous opinion of competent experts employed by the Crown was, that the metal of the fragments that were found in the immediate vicinity of the fracture of the first spinal vertebra was in every respect similar to that of the conical balls found in the undischarged chambers of the revolver.

## QUEEN'S UNIVERSITY IN IRELAND.

AT a meeting held on November 22nd, the Senate elected the following as Examiners during the academical year 1872-73. *Medicine*, Nicholas Colahan, M.D.; *Surgery*, John K. Barton, M.D.; *Midwifery*, T. More Madden, M.D.; *Materia Medica*, Thomas W. Grimshaw, M.D.; *Medical Jurisprudence*, Edmund W. Davy, M.D.

## PATHOLOGICAL SOCIETY OF DUBLIN.

AT the opening meeting of this, the thirty-fourth annual session, which was held on November 25th, the President, Dr. James Stannus Hughes, announced that the Council had selected as the subject for the prize essay "The Diagnosis and Pathology of Injuries of the Thorax and its Contents." An amendment having been moved by Dr. Atthill and seconded by Dr. Bennett, the election of officers was postponed until Saturday, December 9th.

## AUSTRALIAN MEAT.

THE use of Australian meat is rapidly extending in Ireland. Last week it was brought before the notice of the Belfast Board of Guardians. Meat is not a staple article of diet in Irish workhouses; but no doubt if it could be supplied at a cheap rate and of good quality, it would be generally adopted. At the present time, every endeavour to supply good and wholesome meat at a moderate price should be encouraged in the interests of the lower and middle classes.

## THE SANITARY STATE OF DUBLIN.

THE paper read by Dr. Grimshaw before the Medical Association of the College of Physicians, which we published last week, appears to have directed the attention of the Dublin press towards the sanitary condition of that city. *Saunders's News Letter* informs us that "the sewage, main drainage, and other sanitary reforms must ultimately and shortly take place in Dublin;" whilst the *Irish Times* asserts that "the representations which have been made to us (*Irish Times*) leave no doubt that this scandalous state of things will not be much longer tolerated by the citizens of Dublin, who are taxed heavier than the citizens of almost any city in the empire, only to find their legitimate interests neglected." Now that the press has really taken up the subject, there may be some hope that sanitary reform may take place in Dublin. The citizens of that city must be a long suffering generation indeed, that they have not taken the matter before now into their own hands, and brought it before the notice of the Lord-Lieutenant, who is a well known sanitarian, and is empowered to investigate all such matters, in the event of the nuisance authorities neglecting to abate nuisances.

## SPECIAL CORRESPONDENCE.

## LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

*Appointment of a Public Analyst.—Relapsing Fever.—Contagious Diseases Acts.*

THE Health Committee, by a majority of eleven to two, have resolved to recommend the Town Council to appoint a public analyst. The opposition was on the score of economy, the estimated cost of the measure being about £200 a year. Dr. Trench had asked for the appointment in consequence of the suspected importation of poisonous cheese from America. Dr. J. C. Brown, D.Sc.Lond., Lecturer on Chemistry at the Royal Infirmary School of Medicine, has been spoken of as a candidate.

Relapsing fever is slightly on the increase, but can scarcely be said, so far, to have assumed the proportions of a formidable epidemic, although the prospect of continued hard weather, with its invariable sequence, in this town, of want of employment and severe distress amongst the operatives, will inevitably aggravate the severity and extend the ravages of the disease.

A public meeting has been held in this town in furtherance of the objects of the National Association for the Repeal of the Contagious Diseases Acts. Dr. Burrows of Liverpool occupied the chair; and on the platform were several clergymen, Dr. Bell Taylor of Nottingham, a few medical men of this town, Mrs. Josephine Butler, and Mr. Applegarth. The speeches and arguments were of the usual character, except that one of the speakers, Professor Newman, said "he thought they might look forward to a not distant time, when the feeling of this nation would rise to such a point respecting the Contagious Diseases Acts, that it would be remembered against medical men which side they took in the present controversy." One of the speakers, a medical man, was understood to say that, at one of the largest meetings of the Medical Institution at which he had ever been present, and where a discussion took place on the Contagious Diseases Acts, not more than four of those present declared themselves in favour of the Acts—leaving the meeting to infer that a very large majority were opposed to them. Such an inference, however, is scarcely in accordance with the real state of the matter. The question has certainly been brought before the Institution, and a variety of conflicting opinions were expressed by those who took part in the discussion; but, of course, no division was made, such being at variance with all precedent in a scientific debate. So far as the predominant feeling of the members could be known, we are disposed to think that a decided majority would be in favour of a continuance of the Acts amongst the military, although much doubt was expressed as to the practicability of extending them to the civil population in their present form.

## MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

*Purification of the Irwell.—Lecture by Dr. Rumsey.—Amalgamation of the Infirmary and St. Mary's Hospital.—School of Medicine, etc.*

THE new Mayor of Salford is likely to gain our golden opinions if he carry into action his professed intention of purifying the Irwell; but he is likely to meet with difficulties and obstacles in the fulfilment of the design not only from disbelieving ratepayers, but also from the men of science, half a dozen of whom advocate as many different methods of killing or curing the evil. But it is a great step for the chief magistrate to acknowledge his responsibility for the death-dealing character of the stream which flows through the midst of our city.

We have been engaged in other sanitary matters than this dismal river question of late. Last week, Dr. Rumsey read a paper at the invitation of the Manchester Statistical Society "On Certain Fallacies in Local Rates of Mortality." Both in the paper and in the discussion which followed, the Registrar-General was sharply criticised for his statistical deductions. One speaker described his annual report as a thrilling sensational romance, perhaps rather less interesting than one of

Miss Braddon's, but quite as fanciful. It was decided that a committee should be formed for the purpose of drawing up an amended form of death certificate, the adoption of which should be pressed upon Dr. Farr.

Dr. Rumsey's paper is particularly worthy of notice just now, as one of the most important conclusions at which he arrives, and one which is generally accepted as a sanitary axiom at the present day, is in danger of being practically ignored by those who should be the pioneers of sanitary progress, instead of obstinate perpetrators of acknowledged evil. I refer to the erection of intramural hospitals. Dr. Rumsey maintains that "hospitals, and slaughter-houses, and graveyards should, as a rule, be located *extra urbem*, and many of our old collections of sick should be swept away." In spite of this, there is a scheme afloat of amalgamating St. Mary's Hospital for Women and Children with the Infirmary, which means adding a maternity ward to the already sufficiently crowded space in which the Infirmary stands. It is true that there is opposition to this plan on the part of the merchants in the vicinity, many of whom have signed a protest against any more sick wards being built beneath their windows. They, however, are not likely to suffer, beyond having the sign of a favourite hotel interfered with, or the view of Piccadilly flags still further intercepted; but the real sufferers are likely to prove those for whom hospitals are ostensibly built—the sick who enter them. This particularly applies in the case of maternity wards, as Dr. Rumsey clearly enough pointed out in the following passage. "(1) The deaths in hospitals and other large institutions, especially the mortality following operations, and *universally that after childbirth*, are vastly increased by the mere aggregation of patients, and, *ceteris paribus*, in proportion to the density of that aggregation, apart from all other circumstances which might affect success or endanger life; (2) the death-rate, calculated as it should be, on the number of patients, and not on the number of beds, increases with the size of the establishment and the number of its inmates; and (3) wherever this assemblage of the sick and hurt occurs in the centre of a crowded population, the ratio of mortality attains its maximum." It is not probable that any one would be so hardy as to deny the truth of these propositions; at the same time, it is quite comprehensible that the Infirmary staff should desire to add facilities to the students for studying diseases of women and children. There is also another advantage which would indirectly flow from the union—the first blow would be struck at the monopoly of professional appointments which the Infirmary staff have long practically enjoyed.

The Manchester School is now much the largest in the provinces, and is, indeed, larger than many London schools. There are at present 106 registered students in the anatomy class alone, 65 of whom have taken out dissection cards. One of the great advantages of the Manchester School has always been the abundance of subjects; *e.g.*, in 1869-70 there were 43 distributions, and in 1870-71 there were 37. This abundance of the raw material is so constant, that the authorities took no thought for the morrow, by preserving bodies prior to the opening of the school, a proceeding which the recent Act allows. This neglect is somewhat to be regretted as, for the first time for many years, there is a dearth of subjects at the School. No pains, or indeed expense, have been spared by Mr. Smith to render his course of lectures on practical physiology a thorough and complete one. At present, he is demonstrating the histology of the tissues, and at each lecture employs a dozen or fifteen microscopes to assist his class in following his description.

There are many cases at the Infirmary at present of a highly instructive nature to gentlemen commencing the study of surgery; perhaps the most interesting of all is a case of Mr. Lund's of amputation at the ankle-joint (Syme's), which has healed without suppuration or the least loss of substance in three weeks, a result which is all the more remarkable as the operation was undertaken for caries of the tarsus, and several sinuses had for a long time kept up an exhausting discharge. The stump was dressed antiseptically, and covered with many layers of carbolised gauze, which filter but do not exclude the air.

## VIENNA.

[FROM OUR OWN CORRESPONDENT.]

*Politics and Professorships.—The Pathological Institute.—Renal Diseases.*

THE political troubles of Austria do not involve its hospital further than that the successor of Oppolzer is not yet forthcoming. Though Hohenwart has passed away as one of the many ministers of Austria, his policy is far from defunct, but seems even very lively, in other matters as well as in appointing professors great in politics, as German

professors are. Bamberger, of whom much has been spoken in this matter, was once an assistant with Oppolzer, and is usually spoken of as the cleverest man in Germany of his years in medicine. Under such an impression, it is no wonder that the medical division of the University of Vienna wish to secure him for their school. But no discussion, comparatively, would have taken place on this matter, had not the German population of Austria felt it to be a deliberate insult on the part of the Czech or Bohemian ministry then in power. No one can reside in an empire like this, which is still essentially feudal, and which was built up by military supremacy in mediæval times, without feeling how surely with the voice of truth Knox spoke, in his *Races of Man*, of the importance of race unity in the people of a nationality. However, Imperialism is useful in some respects, and the absence of the pressure of public opinion establishes Vienna as the best field for studying the natural history of disease, and provides for her the most ample material for pathological observation in the world. The perfect obedience of the patient to the professors, itself a vestige of the feudal submission to a social superior, enables different measures to be tested from which something is learnt, even if it be only the knowledge of the inutility of many.

The Pathological Institute is a new structure, and is well contrived. On the upper floor are the rooms of Rokitsansky, with lecture-room, Stricker, etc., and the Pathological Museum. On the ground-floor are the general *post mortem* room, in which ordinary cases are examined by the assistant professors, the room for the legal and police cases, immediately presided over by Rokitsansky himself, and also rooms especial to each clinical professor, where cases peculiarly interesting, or where there may have been special difficulties in diagnosis, are examined, without the crowd of spectators interfering with the ordinary routine. The opportunities for observing the pathological changes of disease here are not neglected by the Anglo-Americans, who are frequently in excess of the Germans in the dead-house. The proportion of chronic kidney-mischief is very great, and tends to tell unmistakably what a great effect this must have on the diseases of mature and advanced life. There can be no doubt that the origin of disease in advanced life must lie largely here, and must be regarded, in the language of Bence Jones, "as mechanical results of chemical changes." This theory may not be acceptable to those who attribute local disease to derangements of trophic nerves, but "the unpleasantness of a statement can hardly be regarded as a proof of its falsehood"; and unless we can be taught to regard the function of the kidney as of little importance, and, therefore, the incompleteness of its functional duty as of small moment, it is impossible to see so much of extensive chronic kidney-mischief without concluding that there must have occurred disturbances in consequence, or, in other words, manifestations of its existence. Nor can any great majority of these cases be regarded as cirrhosis; in fact, the kidneys muddle up their diseases in a very provoking manner here, and very disturbing to the divisions of Virchow accepted in England. The Americans, many of whom are very well up, regard the pathology of Roberts with more favour than the more marked divisions of some of our recent writers. Stone is, however, not common here, and one case recently was lithotripped by Billroth, who brought out the bulk of the stone in powder betwixt the blades of the lithotrite. The patient died with croupous inflammation of the bladder, and extensive disorganisation of the kidneys from pyelitis. In one case recently in the dead-house, a kidney had a number of cysts, in which were several black uric acid calculi, some of the size of lentil seeds. There is nothing, however, to identify disease, and especially lithiasis, with the use of the wines here, whether subacid or sweet.

## ASSOCIATION INTELLIGENCE.

### EAST YORK AND NORTH LINCOLN BRANCH.

THE next quarterly meeting of the above Branch will be held at the Hull Infirmary, on Tuesday, December 5th, 1871, at 4 P.M.; J. A. LOCKING, Esq., President, in the Chair.

ROBERT H. B. NICHOLSON, *Honorary Secretary*.  
21, Albion Street, Hull, November 18th, 1871.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

A MEETING of this Branch will be held in the Theatre of the Midland Institute, Birmingham, on Thursday, December 14th, at 3 P.M.

A meeting of the Council of the Branch will be held in the same place at 2.30 P.M.

On the same day, and in the same place, the Committee appointed by the Branch for making arrangements for the annual meeting of the

British Medical Association, will meet immediately after the Branch meeting.

T. H. BARTLEET, *Honorary Secretary*.  
Birmingham, November 26th, 1871.

### SHROPSHIRE SCIENTIFIC BRANCH: ANNUAL MEETING.

THE annual general meeting of the above Branch was held in the Museum of the Natural History Society, Shrewsbury, on October 27th—J. D. HARRIES, Esq., President, in the Chair.

In opening the meeting, the Chairman regretted that the President-elect, Mr. Jones, was unable to take his place, in consequence of an accident which had befallen him. Dr. Moorhouse, however, had most kindly offered to fill his place.

*Officers, etc.*—The following were elected:—*Vice-President*: H. Nelson Edwards, Esq. *Member of the Parliamentary Committee*: J. D. Harries, Esq. *Representatives on the General Council*: H. Johnson, M.D., and S. Wood, Esq.

*New Members.*—Four new members were elected.

*Papers and Cases.*—1. Mr. J. D. HARRIES read a paper on Skin-Grafting, and exhibited some coloured Photographs; also a communication from Mr. Spencer Watson on Dry Dressing of Wounds.

2. Mr. WOOD read a paper from Dr. Newman of Stamford on the Antiseptic Treatment as applied to Operations and Wounds. (This paper has been received for publication.)

Dr. BURD exhibited a case of Tinea Favosa nearly covering the whole surface of the body, and made some observations on the treatment.

4. Mr. WOOD read a paper on Nerve-Force in Waste and Supply.

5. Mr. PHILLIPS exhibited a large and varied collection of Fresh Fungi, and gave a lucid, interesting, and amusing, account of their peculiarities, distinguishing the edible and poisonous kinds.

6. A good collection of Instruments, Medicines and Appliances, and Scientific Instruments, were shown.

*Dinner.*—At five o'clock forty-seven gentlemen assembled at dinner, under the presidency of Dr. Moorhouse; H. Nelson Edwards, Esq., occupying the vice-chair. A most agreeable evening was spent.

## REPORTS OF SOCIETIES.

### PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 21ST, 1871.

JOHN HILTON, Esq., F.R.S., President, in the Chair.

*Epithelioma.*—The PRESIDENT referred to the cases of epithelioma which had been brought before the last meeting of the Society by Mr. Hulke, and gave some particulars of an analogous case which had been treated by Sir Astley Cooper fifty years ago, and had since come under his own notice. The subject of the disease was a gentleman, who suffered from an active epithelial growth over the shin-bone. As he wore knee-breeches and silk stockings, and as the disease caused considerable disfigurement, he was anxious to have it removed. He was jocularly recommended to use a bone-raspe, advice which he actually put repeatedly into force; and although its use produced pain, he by this means kept the growth down for years. A few years ago this gentleman consulted Mr. Hilton for cancer affecting the bone, from which he ultimately died.

*Intracranial Aneurism.*—Dr. DICKINSON exhibited a small aneurism affecting the left middle cerebral artery. The patient was an elderly female, 72 years of age, who had always enjoyed good health. She expired suddenly while at dinner, her head falling on her plate. The effusion on the brain was not sufficient to cause death by cerebral pressure: Dr. Dickinson believed, therefore, that she had died of shock. The arteries of the brain were rather atheromatous, but elsewhere they were not very much affected. The heart and coronary arteries were healthy. The chief interest and rarity of the case was its proving fatal so suddenly.—Dr. GREEN related the case of a gentleman, aged 38, who had died suddenly from cerebral aneurism while drinking a glass of sherry.—Dr. HUGHLINGS JACKSON had seen a case prove fatal after a convulsive seizure in five minutes. There was rupture of an aneurism of the middle cerebral artery.—Dr. DICKINSON, in answer to Dr. JACKSON, stated that there were neither vegetations on the valves, nor any history of convulsions.

*Double Optic Neuritis.*—Mr. BRUDENELL CARTER exhibited by means of the reflecting ophthalmoscope in the ante-room a case of double optic neuritis in a man. He said that Dr. Hughlings Jackson, who had examined the patient, believed that a cerebral tumour was

present, but that the cerebral symptoms were in abeyance.—Dr. JACKSON remarked that there were no cerebral symptoms of moment, hence the interest of the case. It was just one of those cases in which cerebral tumour was found after death without many symptoms during life.—Mr. HULKE pointed out that tumours growing inwards upon the brain gradually produced waste, and that there were often no symptoms until a few hours before death. We should be careful, therefore, in attacking tumours on the outside of the skull, as we frequently could not tell whether they penetrated or not.

*Aneurism of the Innominate Artery.*—Dr. BÄUMLER brought forward a specimen of aneurism of the innominate artery pressing on the common carotid artery. It chiefly affected the anterior circumference, so that the sac extended upwards to the right and left. The pneumogastric, sympathetic, and recurrent nerves were involved in the wall of the sac. The left recurrent nerve was intact. The specimen was taken from the body of a labourer aged 53. Three weeks previously to death he began to suffer from aphonia; he could not close his glottis, thus showing paralysis of the vocal chords. It was complete on the right and partial on the left. The diagnosis was verified after death, and the muscles of the larynx were found to be thin, pale, and flabby. Dr. Bäumler wished to know if bilateral paralysis of the chords occurred from paralysis of one recurrent nerve.—Dr. WILKS had known several cases where the discovery by the laryngoscope of paralysis of the vocal chord led to the diagnosis of aneurism. At the Veterinary College he had been lately told that roaring in horses was produced by pressure on the recurrent laryngeal.—Dr. CRISP said that aneurism in the horse was very rare. The old notion was that roaring was produced by emphysema, but this idea was now given up.—Allusion being made to the treatment of roars by shot, Mr. HULKE referred to a gamekeeper who, he knew, was in the habit of taking shot for "rising of the lights"; and the PRESIDENT referred to a similar practice of taking vinegar in addition to shot.—Dr. RISDON BENNETT remarked that many horses roared after a certain amount of exertion, and that paralysis of the recurrent laryngeal nerve was only one explanation of the disease.

*Horse-shoe Kidney.*—Dr. DICKINSON exhibited a specimen, for Dr. Hawkes.

*Excision of the Elbow-joint.*—Mr. ARNOTT exhibited a specimen showing the results of excision of the elbow-joint. The subject of the disease was a boy, who had been admitted into the Middlesex Hospital two years ago, when two and-a-half-years old. He had strumous testicle and other symptoms of scrofula. The joint was diseased, and was excised. Considerable portions of the bones were taken away. In two or three months he had fair use of his arm. In September 1870 the testis was removed. In May 1871 the boy showed cerebral symptoms, convulsions, and paralysis, which ultimately carried him off. After death, the osseous tissue of the ulna, radius, and humerus was found to be restored, and the ends of the bone were united by means of strong fibrous bands with cartilage imbedded and apparently becoming bone. The limb was half an inch shorter than the other. In the brain were found three tumours in the right cerebral hemisphere, from the size of a walnut to that of a hen's egg, made up chiefly of cheesy substance and coated with grey transparent material, but there were no miliary tubercles in the brain. The skull was perforated. There was tubercle, however, in the lung. The microscopical examination of the tumour showed it to be similar to lymph-gland structure.—Mr. MAUNDER said that new bone was thrown out in quantity in these cases, because the limb was not allowed to rest.—Mr. DE MORGAN referred to a case, in which the radius had been removed and the ulna had thrown out a large quantity of new bone, which could not be explained by Mr. Maunder's theory.—Mr. WARRINGTON HAWARD asked Mr. Arnott whether he had taken any special care, in excising the joint, to preserve the periosteum, as he had seen, after the subperiosteal method of resection, an unusual generation of bone, in one case so much as to interfere with flexion of the joint. Though he did not think such precaution was necessary in ordinary cases, it seemed to him well adapted to such as, from the extent of the disease, required the removal of a large portion of the bones. Mr. Haward had recently practised that method in such a case with very good results. The mobility of the elbow-joint after resection was generally very good, in some cases even more than the natural movements being obtained. As, for instance, the power of placing the hand flat on the shoulder, which could not be done in the natural condition.—Mr. JOHN CROFT had followed out the plan of saving the insertion of the triceps.—In answer to Dr. DOUGLAS POWELL, who asked how the skull had become perforated, Mr. Arnott replied that he believed the inflammation had extended to the dura mater and skull from the tumours.—Mr. Arnott, in reply to Dr. Bäumler, said he did not know whether the child had suffered from acquired or hereditary syphilis.

*Edema of the Glottis: Laryngotomy.*—Dr. DICKINSON exhibited the larynx and trachea of a man aged fifty-two, on whom laryngotomy had been performed for acute oedema of the glottis. He died ten days after the operation, with pneumonia and symptoms of delirium tremens. There was minute injection of the air-passages below the opening, but above it the mucous membrane was of the ordinary pale colour. This inflamed state was, he believed, the result of the air passing, cold and unmoistened, immediately into the trachea and air-passages. At the Hospital for Sick Children, out of thirty-six fatal cases of tracheotomy, pneumonia was present in seventeen; bronchitis without pneumonia in five; and congestion of the lungs in two. To prevent these complications, he had invented a respirator to be applied to the wound. The plan generally adopted, of making a tent by means of the bed-curtains, and keeping it filled with steam, was not good, as the body was also kept under the influence of the steam, an objection.—Mr. SQUIRE said that he thought diffusing the steam in the room was better than the tent method. He believed that chloroform was not employed so frequently as it ought to be in performing the operation of tracheotomy. The pulmonary affection was, however, not always due to the cold air, as bronchitis naturally arose in many cases in consequence of the disease.—Dr. WILKS agreed entirely with Dr. Dickinson in his opinion about the effects of the operation. He believed tracheotomy to be a formidable operation.—Mr. THOMAS COOKE said he had operated on five cases in Paris, and four of these proved successful. He covered the cannula with a piece of thick gauze. Mr. Cooke also alluded to the case of a gentleman who had worn a cannula for years, and who had an India-rubber-tube attached to the cannula, the mouth of which he kept under the waistcoat, so that the air was thus rendered warm.

#### ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, NOVEMBER 18TH, 1871.

R. DRUITT, M.D., President, in the Chair.

*The Position and Duties of Medical Officers of Health.*—The PRESIDENT read a paper on this subject. He recommended a fusion of the preventive and curative functions—the *non bene junctarum discordia semina rerum*; and the organisation of sanitary districts in such a way as to save labour and time, and to hinder two people from going over the same ground. The Royal Sanitary Commissioners have recommended that there shall be one local health authority in every district, and not more than one; and that every local health authority shall have a medical officer of health—and it is suggested that the Poor-law medical officer shall be that medical officer of health in rural districts; and that every such officer should have the power of an inspector of nuisances. We might rejoice in the hope that preventive medicine will thus be put on a level, if the recommendations of the Commissioners should become law, with curative medicine, and that the powers necessary for abolishing the causes of disease would be conferred on the practitioners who attend the poor. He did not wish to impose new and unpaid duties upon the present holders of Poor-law offices. He denied that their status and emoluments should be raised, and that they should be regarded as "civil surgeons," or have some other attractive title. As the Poor-law Board had been abolished, so should Poor-law surgeons. He hoped that there would be one law for the whole kingdom, and that the civil curative officer would everywhere work with and under the medical officer of health. Higher qualifications ought to be exacted from the medical officer of health—his duties ought to be more of an inspectorial order, and less compatible with general practice. Speaking of inspection he said that he had always regretted the want of inspectorial visitation by a superior authority, who should harmonise the work of various parishes, and combine the results of all in one metropolitan sanitary report. There would be immense benefit if the actual civil surgeons were subject to visitation and inspection by medical officers of health, and if medical officers of health were themselves subject to the same control from a central office, and if for this purpose every institution—be it hospital or dispensary—supported by voluntary contributions, which undertakes the treatment of the poor, were placed in the same category. The only defect he saw in the recommendations of the Royal Sanitary Commissioners was the want of some consulting and inspectorial referee nearer than the Local Government Board in London. The duty of reporting on local and scattered insanitary conditions, and the recommendation of remedies, ought to be the duty of the civil surgeon, whose duty it should be to act as sanitary or preventive or health officer in the first instance. But he must make it his duty, when he sends in his sickness report, to say whether any insanitary conditions exist, and whether proper notices have been served, and if not, why not. The medical officers of health,

or superior civil practitioners would relieve the ordinary civil surgeon of the trouble of initiating law proceedings, and of the embarrassment of offending his friends and patients. The possible duties and qualifications of the medical officer of health or civil inspecting practitioner were multifarious. It is to him that the public would look for statistical information as to sickness and death, and their causes, over the area of his jurisdiction; for initiating and carrying out legal proceedings against nuisances; for inquiring into cases of uncertified deaths. Moreover, he should conduct *post mortem* examinations, make analyses, test adulterated food, determine the purity of water, act as coadjutor or substitute for the coroner, and report on epidemics affecting animals. The sanitary officer, if he be not to fall behind the age, must have some kind of study which shall connect him with the progress of biological science in some branch. As to the holding of private practice it would be limiting the choice of officers unduly if all degrees of private practice were disqualifications. The ideal combined curative and sanitary medical organisation which Dr. Druitt advocated was foreshadowed by the arrangements in some rich London parishes thirty years ago. For instance, the parish of St. George, Hanover Square, used to employ a physician and surgeon with handsome salaries, besides the general practitioners. The last holders of those offices were Sir James Clark (then Dr. Clark), who resigned on being appointed Physician to the Queen; and Mr. Howship, who was Surgeon. Dr. Druitt concluded with some comments on the progress of cholera at Constantinople and elsewhere.

Dr. ILIFF moved a vote of thanks to the President for his paper.—Dr. LETHBY, in seconding the vote, said the paper was a most opportune one. It was necessary, however, to be very careful with regard to the Poor-law medical officers. They possessed most valuable information, but it was doubtful whether they could properly perform so many duties, unless they had some superior officer over them. In some towns, owners of poor property were sometimes among the Poor-law officer's best patients, and he ought to have somebody to screen him. Information was needed as to the sickness of the people, and the Poor-law medical officers were the best able to furnish this, if it could be properly managed.—Dr. DUDFIELD believed that the Poor-law medical officers would be quite satisfied with the position of assistant medical officers of health. He quite agreed that owners of poor property were frequently members of boards of guardians. He had heard of money being given as relief with the one hand, and taken back as rent with the other. During the epidemic of 1866, he had witnessed highly beneficial results arise from the harmonious working together of the medical officer of health and the Poor-law medical officers. He believed that at present they had power to inspect the Poor-law officers' books, at least in those parishes in which the dispensary system had been established. Moreover, the imparting of such information would tend to diminish sickness, and consequently to lighten their own labours.—Dr. HARDWICKE said, with reference to the contagiousness of diarrhoea, that he had found by practical experience that the temperature had more to do with the spread of the disease than surrounding nuisances. He had also noticed that the diarrhoea of summer was replaced by bronchitis in winter in nearly the same proportion.—Dr. STEVENSON concurred in thinking the Poor-law medical officers could give valuable assistance, and he thought they would be entitled to extra pay for their services.—Dr. GIBBON had received great assistance from the reports of the Poor-law medical officers. He thought, however, that to be efficient they ought to be released from private practice.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, NOVEMBER 25TH, 1871.

JAMES STANNUS HUGHES, M.D., President, in the Chair.

*Amyloid Degeneration.*—Dr. WILLIAM MOORE presented a group of specimens of amyloid degeneration taken from the body of a soldier, aged 28. There was some doubtful history of two attacks of syphilis in the case. About eighteen months ago, the patient began to suffer from epigastric pain, cough, and expectoration. A year back, he vomited blood, but in no great quantity. On admission, he was extremely emaciated, with a dusky hue over the face and body. There was a considerable amount of ascites, the measurement round the body at the level of the umbilicus being more than forty inches. The urine was free from albumen. He shortly died of exhaustion. The liver was enlarged, and weighed eight pounds. Its transverse diameter was fourteen inches. It afforded a good example of the lardaceous liver, responding freely to the iodine test. The kidneys and spleen had also undergone amyloid degeneration. The heart was fatty, and the lungs were extensively diseased; the left viscus presenting an extreme degree of cirrhosis, and a cavity being found in the apex of the right lung.

*Disease of Knee: Amputation.*—Mr. JOHN HAMILTON brought before the meeting an example of chronic disease of the right knee-joint, necessitating amputation through the lower part of the femur. A man, 20 years of age, suffered from symptoms of knee-joint disease. Violent starting pains in the neighbourhood of the knee were followed by the formation of an oval swelling, in which fluctuation shortly became established. A group of unusually severe constitutional symptoms also made their appearance. The disease had commenced six years before, as an attack of synovitis. Owing to judicious treatment, the affection was kept in abeyance for a long time, but unfortunately the patient fell and fractured the lower end of the femur. This accident led to the development of symptoms of ulceration of the cartilages, and to the formation of an abscess below the popliteal space. After removal of the limb, the following morbid changes were noticed. On opening into the joint, a quantity of dark coloured pus escaped. Ulceration of the cartilage of the patella had made great progress, and the cartilage over the femoral condyles and over the outer condyle of the tibia was quite eroded; that over the inner condyle was in an ulcerated state. Pulpy thickening of the synovial membranes had occurred, and some evidence of the line of fracture of the femur was obtained.

*Latent Aneurism: Fatty Disease of the Heart.*—Dr. HAYDEN detailed an important case of latent aneurism and fatty disease of the heart, and exhibited the morbid specimens connected with it. A gentleman, aged 62, had suffered about three years ago from lumbar rheumatism. He subsequently remained pretty well, though he was occasionally a victim to neuralgia. On the afternoon of November 10th last, he consulted Dr. Hayden for this latter affection. The pulse was full and regular, at 84. The heart's sounds were almost normal, the first being perhaps slightly ill-pronounced, and the second rather unusually sharp in tone. There was, however, nothing especially to attract attention. Dr. Hayden turned to his desk to write a prescription, when a rustling sound was heard, and he observed the patient fall senseless to the ground. In a short time he was dead. At the necropsy, the anterior mediastinum was discovered laden with fat. The pericardium was filled with dark clotted blood, and the anterior surface of the heart had a yellow hue. A rent was found in the right side of the aorta just where this vessel leaves the pericardium. The highly atheromatous internal coat had evidently first given way, and the increasing pressure of blood had then caused the rupture into the pericardial sac. An aneurism, in shape like a pine-apple, ran up the ascending aorta, but did not engage the great vessels springing from its arch. The internal surface of the dilatation was very rugose. The muscular fibres of the heart were in a state of obsolescence, and in places had quite disappeared, nothing being visible under the microscope but large fat globules. The change, on the whole, seemed to be one of fatty substitution rather than of fatty conversion.

## CORRESPONDENCE.

### SEWAGE AND ENTOZOA.

SIR,—Dr. Alfred Carpenter is correct in surmising that I have not visited the sewage-works at Croydon; nevertheless, being guided by the statements of others who have visited the irrigated district, I do not see how I could arrive at any other conclusion than the one stated by me in the extemporised speech referred to. I respectfully submit that the following data imply that the irrigated grounds at Croydon and Beddington are flat, "low-lying", and "swampy."

I must premise that I based my statements chiefly upon the recollection of what took place at three separate meetings of the Association of Officers of Health, when Dr. Letheby, Mr. Hawksley, Mr. Smee, and Mr. Creasy, characterised the state of things at Croydon as little better than a "pestilential swamp."

On referring to Dr. Letheby's paper, and report of the discussion which took place on one of these occasions, I do not find that my memory has been particularly unfaithful. He says, speaking of all such districts (p. 9):—"The land irrigated with sewage is always a fetid, swampy morass, of the most offensive description." "At Norwood and Beddington it is a subject of serious complaint." "I have been surprised at the statements of Dr. Carpenter."

Again, Mr. Creasy's evidence before the Parliamentary Committee is quoted (p. 9):—"I know the sewage-farm belonging to the Croydon Board of Works, and have had experience of what condition of health is around those flats." In the discussion, Mr. Creasy added (p. 18):—"As to the outfall at Beddington Corner, every well was contaminated." "The grass was irrigated as long as it could stand up, and then it was sent away to market, with the sewage some inches up the stem."

Mr. Hawksley said (p. 18):—"In the month of February he was down there. The sewage was then *frozen over the whole surface of the land* for acres and acres, and was not in the state Dr. Carpenter described."

In reference to Dr. Letheby's assertion that sewage-farms are "pestilential swamps". Mr. Hope also says (BRITISH MEDICAL JOURNAL, p. 374):—"I believe that this is a very accurate description of many, and I even fear of most, sewage-farms." "The scythe, as a rule, does not descend as low as the height to which the sewage rises on the stems. *I except, of course, all improperly managed farms, such as Croydon.*"

In the face of the combined evidence here referred to, I think Dr. Alfred Carpenter is unduly angry with me for forming the very natural and legitimate deduction which I did.

As regards the dissemination of the germs of entozoa, I may say that, if all sewage-farms were laid out and conducted in the admirable manner in which Mr. Hope's Breton farm is well known to be, certain of these parasites would stand very little chance of propagating their species. In my humble judgment, the agriculturalists are deeply indebted to that gentleman.

What Dr. Carpenter means by the expressions "innuendos frequently cast out", and "promoters of a patent", I do not know. The tone of his letter is neither dignified nor gracious.

I am, etc., T. SPENCER COBOLD, M.D., F.R.S.

Wimpole Street, November 24th.

#### MEDICAL EXAMINATIONS.

SIR,—With a view to the publicity which you advocated in your leading article on "The Coming Race" in last week's JOURNAL, I would venture to suggest that all medical students should be permitted to attend and hear the *viva voce* examinations of the various licensing bodies. At Oxford, and I believe at Cambridge, all *viva voce* examinations whatsoever are public. Indeed, some years ago, to sit in the schools whilst these were going on was as much a part of an undergraduate's duty as attendance on lectures; and students avail themselves largely, and to their great advantage, of this privilege; and, since examinations are set up as standards of acquirements, should not every facility be given to students for obtaining clear ideas of the nature and height of these standards? The papers set, it is true, are easily obtainable; but these give no idea of the equally or perhaps more important practical and *viva voce* part of the examination. I have never heard, and should be at a loss to imagine, any valid reason for the inquisitorial secrecy with which the examinations are conducted at the College of Surgeons, and even at the University of London, from which one might have expected a more liberal treatment. If a student do not know his work, nothing he will hear on the days of his examination from the *viva voce* of others will get him through. And surely there can be no fear with the examiners of running dry of questions in subjects so wide, and of which they are such accomplished masters. It is perhaps a weakness with medical students, that they have not a sufficient control over their emotions; but the solemnity of the occasion and the august presence of the examiners would have a subduing effect, and any indecorous manifestation of feeling would have to be promptly put down. The fear of making a fool of himself before his fellows might have a salutary stimulant effect on some students.

I am, etc., M.A., M.B. OXON., M.R.C.S., L.S.A.

Tealby, November 28th.

## THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

SIR,—Permit me to urge once more upon the members of the Poor-law Medical Officers' Association the necessity for paying their subscriptions, which are long over-due. The amount has never been large for the good done, and being done, and the bulk of the members have never been asked to contribute any labour. Dr. Rogers, Mr. Corrance, and a few others, who have not one single farthing to gain by their exertions, have been working unremittingly for months and years; and the great body of the Association, who have everything to gain, are only asked for five shillings each! Is it possible that they can hang back, now that the Bill embodying the objects they have had in view is already drawn up, and in the hands of Mr. Corrance, who is going to introduce it into Parliament next session? The total cost of the Bill will be less than the amount of subscriptions already due and

unpaid, and the workers in this movement have a right to expect that their hands shall not be tied by paltry considerations of *£ s. d.*

The members of the Association in Cardiff and neighbourhood have voluntarily increased their subscriptions to seven shillings and sixpence; not that the amount is a great deal, but if in a poor Welsh union this can be done, it surely ought to stimulate other members to go and do likewise. There would then be a sum in hand more than sufficient for all our needs.

Mr. Corrance, in addition to the time and trouble he has devoted to this cause, has nobly offered to bear a large share of the expense; but shame must surely operate on the members of the Poor-law medical staff throughout the land to prevent such a necessity. If they cannot bear the cost of carrying on their own work, when that cost, too, is so ridiculously small, they ought never to have become a Society, nor have encouraged other and more earnest men to depend upon such a broken reed as their support.

JAMES MILWARD.

Cardiff, November 28th, 1871.

#### POOR-LAW MEDICAL FEES.

MEDICUS writes:—I saw in the last number of your JOURNAL a copy of the consolidated order of the Poor-law Board, in which I feel interested, and should like to know whether a board of guardians is justified in refusing a fee for medical attendance in a midwifery case after the medical officer of the district had received an order from the overseer to attend the case?

The person who was attended did not actually receive parochial relief, but the overseer knew that the party referred to had not sufficient means to pay for a medical attendant, there being a family of six young children, and the husband only earning about fifteen shillings a week. I shall be glad to know whether the overseer or guardians are liable for the fee in such a case.

\*\*\* The law empowers overseers to grant relief only in cases of "sudden and urgent necessity;" and, therefore, if an overseer should give an order for medical attendance, it is his duty to satisfy himself whether the case be such an one as he is legally entitled to relieve—that is, whether it be a case of "sudden and urgent necessity." If the medical officer receive from the overseer an order to attend a case, and the case be one for which the overseer is not empowered to issue an order, then the medical officer may act upon the order or not, as he may think fit; requiring, if he act upon it, that the overseer giving the order shall undertake personally to remunerate him for his services. When the medical officer, having attended in pursuance of an order issued by the overseer, makes his claim to the guardians for a fee under Art. 182, the guardians must ascertain whether the claim be well founded. If they come to the conclusion that the order was not lawful, they must then hold that the medical officer is not entitled to a fee from them, and they would be bound to withhold it. At the same time, certain discretionary power is allowed to the guardians; and they may deal with the case as one justifying such compensation as they may think proper to make, in accordance with the terms Vic. 11 and 12, cap. 110, sect. 2. On the other hand, the medical officer has a legal claim on the overseer if the latter directly, or by implication, undertook a personal responsibility in respect of the medical officer's attendance on a case for which he had issued an order.

## OBITUARY.

### JOHN DEMPSTER, M.D., INSPECTOR-GENERAL OF ARMY HOSPITALS.

DR. DEMPSTER died recently in Edinburgh at the age of 77. He was the son of a medical practitioner in Cupar-Fife, and was one of seven brothers, most of whom have served in the army as medical officers. He entered the army as hospital assistant-surgeon in October 1813, and served five years at the Cape of Good Hope. In 1821 he was attached to the 72nd Foot, and afterwards to the 38th, with which regiment he served during the Burmese war from 1824 to 1826. For his services here he received the silver medal and clasps. He was surgeon to the 62nd Regiment in India until 1848. In 1852, the rank of Deputy Inspector-General was conferred upon him, and he was sent to Jamaica to assume the control of the medical department in that colony. On leaving, he received the thanks of the Government for his care of the troops, and for his judicious hospital reforms. By the Royal Warrant of 1858, he was placed on half-pay. Shortly afterwards, he received the good service pension. His long service in warm climates had impaired his constitution, and after a short illness he succumbed to an attack of asthma and bronchitis.

## HENRY GREENWOOD, M.D., BLACKHEATH.

DR. GREENWOOD was born in 1793, at Calne, of which place his father was vicar. He was apprenticed at the proper age to Mr. Corfe, a surgeon in Southampton; and afterwards became a student of the then united hospitals of Guy's and St. Thomas's. He became a Member of the Royal College of Surgeons in 1814, and soon afterwards entered into partnership with Dr. Brickenden, a general practitioner in Horselydown and the neighbourhood, on whose retirement he succeeded to the practice. In 1842 he took the degree of M.D. at the University of St. Andrew's; in 1852 he was made a Fellow of the Royal College of Surgeons of England, and in 1859 a Member of the Royal College of Physicians of London. After some years of weakness and suffering, he expired at Blackheath, on November 22nd. Dr. Greenwood was one of the original members of the Hunterian Society.

THOMAS ANNANDALE, M.R.C.S., L.R.C.S.E., L.S.A.,  
Consulting Surgeon to the Newcastle-on-Tyne Infirmary.

MR. ANNANDALE died suddenly, aged 62, at Wetheral, near Carlisle, of apoplexy, on November 14th. He was for many years a surgeon to the Newcastle Infirmary, and had an extensive general practice in Newcastle and the surrounding districts. He was compelled to relinquish his practice about five years ago, owing to an attack of paralysis; and since then he lived a retired life at Wetheral. Mr. Annandale was distinguished as an operating surgeon, and enjoyed the esteem and respect of his patients, who thoroughly trusted him, for his treatment of them was always honest and upright. By the poor he was much beloved; and he often received grateful and kind expressions from hospital patients who had experienced his tenderness and had benefited by his skill. On retiring from the Infirmary, Mr. Annandale was appointed consulting-surgeon to the institution, a compliment which he sincerely valued.

## MEDICAL NEWS.

## ROYAL SOCIETY.

At the Annual Meeting of the Fellows of this Institution on Thursday last (St. Andrew's-day), the Officers and Council for the ensuing year were elected. On this occasion, the medals were presented to Mr. George Busk, President of the Royal College of Surgeons, for his valuable researches in Comparative Anatomy, Physiology, and Zoology; to Dr. Stenhouse for his researches in Chemistry; and to Mr. Mayer for his researches on Heat. Professor Airey, the Astronomer Royal, was elected President of the Society in the vacancy occasioned by the retirement of General Sabine, who has filled the office for ten years, and who, it will be recollected, succeeded the late Sir Benjamin Collins Brodie, Bart. In the evening, the Fellows, upwards of a hundred in number, dined together, the Lord Chancellor and other distinguished visitors being present.

It is not generally known that the Royal Medals, of the value of twenty guineas each, annually presented by the Society, are a gift, and that their cost is paid from the privy purse of Her Majesty.

## ASSOCIATION OF CERTIFYING MEDICAL OFFICERS.

THE fourth annual general meeting of the Association was held at the Adelphi Hotel, Liverpool, on October 20th last; Dr. ARLIDGE, the President, in the Chair.

In the report of the Committee, reference was made to the new regulations respecting the reporting of accidents, which were generally approved of. The Committee considered, however, that the fee of sixpence for examining each factory hand presented at the residence of the surgeon, fixed by the factory inspectors, with the sanction of the Home Office, was beyond the scope and meaning of the Acts now in force, and neither creditable for the Government to offer, nor for the surgeon to accept. By sanctioning the examination of children and young persons at the residence of the factory medical officer, the Memorandum had revived a proceeding that experience had proved to be both useless and a cause of irregularity, and which had been repealed in later Acts. The Committee recommended that a short memorial to the Home Secretary be prepared, and sent to every certifying medical officer for his signature, praying for a modification of this order, on the ground

that so small a fee was never before offered for any public service whatever. Even in the case of the registrars of births, etc., the minimum fee for a mere copy of a birth-register, when given on the formal requisition issued by the authority of the inspectors, under a special clause of the Factory Acts, is one shilling, whilst in ordinary cases it is three shillings and sixpence.

The following gentlemen were elected as officers and members of the Committee for the year 1871-72:—President: J. T. Arlidge, M.D., Newcastle-under-Lyne. Vice-Presidents: F. Jordan, Esq., Birmingham; W. Roden, M.D., Kidderminster. Treasurer: E. Waters, L.R.C.P.Ed., Coventry. Secretary: G. M. Stansfeld, Esq., Redland, Bristol. Committee: C. D. Purdon, M.B., Belfast; J. T. Mitchell, Esq., Stockwell, London; T. Bott, Esq., Bury; W. L. Underhill, Esq., Tipton Green; H. Collins, M.D., Wolverhampton; G. W. Hardy, Esq., Warrington; R. Beales, M.D., Congleton; C. R. Crossley, Esq., Leicester; W. J. Clapp, Esq., Nantyglo, Monmouthshire; A. H. Balfour, Esq., Portobello, Edinburgh; C. Johnson, Esq., Lancaster; and R. G. Horton, Esq., Leeds.

A very able and instructive address was delivered by the President, and ordered to be printed with the other proceedings of the Association.

The desirability of all factory surgeons joining the Association was strongly insisted upon at the meeting; and, in order that the general purposes of the Association should be more fully understood, as also the reasons for joining it, it was resolved that the report be sent to all the medical officers under the Factory Act whose names and addresses could be obtained. The next annual meeting of the Association was decided to be held at Bristol, not later than the second week of September 1872. The names of new members should be sent to the Honorary Secretary, to whom also all communications should be addressed.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on November 16th.

Boon, Alfred Pearl, Delamere Crescent (St. Mary's)  
Cable, George Hughes, Royal Hill, Greenwich (Guy's)  
Cowley, John Selwyn, Upton-on-Severn (St. Bartholomew's)  
De Méric, Henry Eugene, Brook Street, Grosvenor Square (King's College)  
Ewart, William, Montpelier Square, S.W. (St. George's)  
Gill, Stanley Augustine, Torquay, Devon (London)  
Harrison, Thomas, Stafford (Liverpool School)  
Head, William Cave, Lewes, Sussex (St. Bartholomew's)  
Hendry, James Alexander, Liverpool (Liverpool School)  
Jago, Thomas, Saltash, Cornwall (St. Bartholomew's)  
James, David Philip, Narberth, South Wales (St. Bartholomew's)  
Johnson, Frederick Phillips, Taunton, Somerset (University College)  
Julius, Stanley Alexander, Mortlake (King's College)  
Lee, Alfred Robert, Tollington Park (University College)  
Sergeant, Edward, Preston, Lancashire (St. Thomas's)  
Smith, Joseph Priestley, Edgbaston, Birmingham (Birmingham School)  
Thomas, John Howell, Carmarthen (London)  
Yate, Edward, Godalming (St. Bartholomew's)

The following candidates were admitted members on November 17th.

Harbinson, Alexander, Newry, co. Down (Belfast School)  
Lees, Frederic Arnold, Meanwood, near Leeds (Leeds School)  
Magill, James, Cork (Cork School)  
Masterman, George Frederick, Croydon (Guy's)  
Ramsay, Ebenezer John, Queen Anne Street (University College)  
Rogers, William Richard, Berners Street (University College)  
Scale, George John, Merthyr Tydfil (Middlesex)  
Slater, John Samuel, Bath (St. Thomas's)  
Sloane, Ebenezer Erskine, Lisburn, co. Antrim (Belfast School)  
Walsham, William Johnson, Tyndale Place, Islington (St. Bartholomew's)  
Wright, John Rowland, The Bank, Leicester (St. Mary's)

The following members of the College, having passed the primary or anatomical and physiological examination for the Fellowship at a meeting of the Court of Examiners on November 21st, will be admitted to the final when eligible.

Samuel Bowen Partridge, H. M. Indian Army, diploma of membership dated August 5, 1851; and John Soelberg Wells, Savile Row, December 21, 1860 (Students of King's College); William Harvey, Royal Navy, January 29, 1862 (Charing Cross); Thomas Alexander Roe, Royal Navy, April 28, 1862 (Cork School); Charles Higgins, Hambledon, April 21, 1865 (Guy's); George Harrison Evans, Hagley Road, Birmingham, April 22, 1868 (St. Bartholomew's, Birmingham, and Edinburgh Schools); Charles Henry Joubert, Newton Lodge, Hungerford, May 5, 1868 (St. Mary's); and Herbert William Page, Carlisle, November 16, 1869 (London).

The following gentlemen, not members of the College, passed the examination.

George Albert Dundas, Guy's Hospital; Horatio Bryan Donkin, St. Thomas's Hospital; Herbert Campbell Moss, King's College; and Benjamin Jones Mansell, Bristol School.

Nine candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 23rd, 1871.

Elkington, Ernest Alfred, Birmingham  
Maybury, William Augustus, Frimley, Surrey

The following gentlemen also on the same day passed their first professional examination.

Donaldson, Henry, Charing Cross Hospital  
Evans, Thomas, Guy's Hospital  
Prothero, David George, Middlesex Hospital  
Utting, James, Guy's Hospital

As an Assistant in compounding and dispensing medicines.  
Hyne, Harry, South Bank, St. John's Wood

### MEDICAL VACANCIES.

**THE following vacancies are announced:—**

**ABERDEEN DISPENSARY**—Medical Officer.  
**AMERSHAM UNION**—Medical Officer.  
**BALLINASLOE UNION**, co. Galway—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Kiltormer Dispensary District: £100 per annum, and Vaccination and Registration Fees.  
**BIRMINGHAM and MIDLAND EYE HOSPITAL**—House-Surgeon: £80 per annum, apartments, board, and attendance.  
**BRADFORD (NEW) FEVER HOSPITAL**—Resident Medical Superintendent.  
**CARNARVONSHIRE and ANGLESEY INFIRMARY and DISPENSARY**, Bangor—House-Surgeon: £80 per annum, board and lodging.  
**CENTRAL LONDON OPHTHALMIC HOSPITAL**—Assistant-Surgeon.  
**CHARING CROSS HOSPITAL**—Assistant-Physician.  
**CLAREMORRIS UNION**, co. Mayo—Medical Officer for the Ballyhaunis Dispensary District: £125 per annum, and Vaccination and Registration Fees.  
**CRIEFF, Perthshire**—Certifying Factory Surgeon.  
**DENTAL HOSPITAL OF LONDON**—Lecturer on Dental Surgery and Pathology.  
**DEVON and EXETER HOSPITAL**—Surgeon.  
**EARLSWOOD ASYLUM FOR IDIOTS**—Assistant Medical Officer: £150 per annum, board and apartments.  
**EXETER LYING-IN CHARITY**—Physician.  
**FARRINGTON DISPENSARY**, Bartlett's Buildings, Holborn—Resident Surgeon: £75 per annum, coal, gas, and apartments.  
**GREAT NORTHERN HOSPITAL**—Surgeon.  
**HOSPITAL FOR CONSUMPTION and DISEASES OF THE CHEST**, Brompton—Resident Clinical Assistant.  
**KILBURN, MAIDA HILL, and ST. JOHN'S WOOD GENERAL DISPENSARY**—Resident Medical Officer.  
**LEEDS HOSPITAL for WOMEN and CHILDREN**—Assistant-Surgeon.  
**LIVERPOOL SOUTHERN HOSPITAL**—Senior House-Surgeon.  
**LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE**—Lecturer on Ophthalmology.  
**MADDERTY, Perthshire**—Parochial Medical Officer.  
**NORTH BIERLEY UNION**, Yorkshire—Medical Officer for the Idle or No. 6 District.  
**NORTH MAVINE and DELTING, Shetland**—Parochial Medical Officer.  
**NUNEATON, Warwickshire**—Certifying Factory Surgeon.  
**NUNEATON UNION**—Medical Officer for the Nuneaton District.  
**ST. MARY'S HOSPITAL and DISPENSARY for WOMEN and CHILDREN**, Manchester—Medical Officer: £60 per annum, board and residence.  
**ST. PANCRAS, Middlesex**—Medical Officer for the Workhouse and Infirmary.  
**SEAMEN'S HOSPITAL** (late *Dreadnought*), Greenwich—House-Physician.  
**UNIVERSITY COLLEGE HOSPITAL**—Assistant Obstetric Physician.  
**WEST BROMWICH DISTRICT HOSPITAL**—House-Surgeon: £70 per annum, board and residence.  
**WEST OF ENGLAND EYE INFIRMARY, Exeter**—Surgeon.  
**WOLVERHAMPTON UNION**—Dispenser: £90 per annum.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.\**

\***BARTLETT, J. J. H., Esq.**, appointed Surgeon to the Kensington Dispensary, *vice* T. O. Dudfield, M.D., resigned.  
**BURR, James, L.R.C.P. Edin.**, elected a Medical Officer to the St. Nicholas Parochial Board, Aberdeen.  
\***DAVIES, John, M.D.**, Surgeon to the Abersychan Iron and Coal Works, appointed Surgeon to the Ebbw Vale Steel, Iron, and Coal Works, *vice* Henry Laxton, Esq., resigned.  
**MULLIGAN, John W., M.D.**, appointed Surgeon to the Abersychan Iron and Coal Works, *vice* John Davies, M.D.  
**SMITH, James A., M.D.**, appointed Medical Officer and Public Vaccinator for the Parish of Cadder, Lanarkshire.  
\***THOROWGOOD, John C., M.D.**, appointed Lecturer on Materia Medica at the Middlesex Hospital, *vice* \*T. L. Brunton, M.D., resigned.

**DONATIONS, BEQUESTS, ETC.**—Mr. Jasper Young, of Singapore, has sent £500 to the Kilmarnock Fever Hospital and Infirmary.—“A Lady” has given £200 to the Hospital for Incurables, Dublin.—The General Hospital and Queen's Hospital, Birmingham, have each received £100 (less duty) under the will of Mr. Wm. Hinkley.—Mr. Bernard Rice has bequeathed to the Charities of Birmingham as follows:—£50 each to the General Hospital, the Queen's Hospital, the Hospital for Sick Children, and the Asylum for the Blind; £25 each to the Eye Hospital and the Sanatorium; £20 to the Asylum for the Deaf and Dumb; and £10 to the Ear and Throat Infirmary.—The Mercers Company have given Fifty Guineas to the Hospital for Women.

### OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**THURSDAY** ... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
**SATURDAY** .... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8 P.M. Mr. Walter Coulson, “Two Cases of successful Transplantation of Skin on extensive Tertiary Ulceration”; Dr. Hughlings Jackson, “A Case of Tumour and Cyst of the Right Lobe of the Cerebellum.”  
**TUESDAY.**—Pathological Society of London, 8 P.M. The following specimens will be exhibited:—Dr. C. T. Williams (for Dr. Quain), Disease of Aorta, etc.; Dr. C. T. Williams, Disease of Suprarenal Capsules in a Phthisical Subject; Mr. A. Norton, Cancer of Larynx; Mr. F. Churchill, Fatty Tumour simulating Ranula; Dr. Green, Interstitial Pneumonia; Dr. Crisp, Cirrhosis of Liver and Baggy Stomach; Dr. Crisp, Disease of Hip-joint and Kidneys.  
**WEDNESDAY.**—Royal Microscopical Society, 8 P.M. Mr. J. Bell, “Fermentation and its Results”; Dr. L. Beale, F.R.S., “The Nerves of the Capillary Vessels and their probable Action in Health and Disease.”—Obstetrical Society of London, 8 P.M. Mr. Eugene Goddard, “On a successful Case of Ovariectomy during Pregnancy”; Dr. Brunton, “On Fibroid Enlargement of the Uterus”; Dr. Edis, “On the Systematic Examination of the Uterus, with the view of rectifying Malpositions of the Fœtus”; Dr. Meadows, “On a Case of Extrauterine Fœtation, with remarks on Treatment.”—Hunterian Society, 8 P.M.: Open Meeting. Council, 9.30 P.M.—Medico-Psychological Association, 32a, George Street, Hanover Square, 8 P.M. 1. Clinical Reports, Morbid Specimens, etc.; 2. Dr. Maudslay, “Is Insanity on the increase?”  
**THURSDAY.**—Harveian Society of London, 7.15 P.M.: Council Meeting (Special). 8 P.M.: Mr. G. G. Gascoyen, “On Spermatorrhœa and its Treatment.”  
**FRIDAY.**—Clinical Society of London, 8.30 P.M. Dr. Ogle, “On the Temperature in certain affections of the Nervous System, and especially in Tetanus”; Dr. Habershon, On Cases of Heart-disease; Dr. Broadbent, Tumour in Left Half of Floor of Fourth Ventricle, with small Tumour in Cerebellum.

### NOTICES TO CORRESPONDENTS.

*ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.*

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS.**—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

For replies to questions concerning Poor-law medical questions, see Poor law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Maunsell, Dublin.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

MR. GILBERT'S letter should be put into the form of an advertisement.

#### MEDICAL QUACKERY.

SIR,—Two paragraphs in your last impression demand a passing notice; the one, the letter of “An Associate” with reference to “The Institute of Anatomy, Birmingham”; and the other, the reference to the prosecution under the Medical Act in Aberdeen. Mr. Forbes is entitled both to professional and public thanks for his prosecution of Frederick Adair, designating himself an M.D.; and it is to be regretted that the Sheriff was obliged to rule that “there was no evidence that the respondent carried on a business as a medical practitioner,” when I am sure scores of such documents as the subjoined must be distributed over the length and breadth of the land. Some time ago, a patient of mine who, in more verdant years, had been entangled in the meshes of the charlatan, fell in with the pestilential book purporting to be written by Frederick Adair, Esq.; and, in order to satisfy himself as to the character of the author, sent him a communication, to which he received the following reply, at present in my possession.

“22, Marischal Street, Aberdeen, 10th August, 1870.

“Sir,—You sometime back applied to me for advice upon your case; not having

heard from you in answer to my communication, I consider it my duty to acquaint you that the nature of your case requires proper and skilful treatment, in order to prevent greater and far more serious evils coming upon you. Neglect or improper treatment will entail the worst results, and you will have yourself to blame for the painful and melancholy consequences that inevitably will ensue. If, however, you at once adopt this infallible remedy, 'The Restorative Mixture,' which I, from long experience, have found so eminently successful in cases precisely similar to your own, I can faithfully guarantee a permanent and satisfactory cure. If you still desire my professional assistance, I shall be glad to send you a supply of 'The Restorative Mixture' of whatever size packet you may think requisite, upon receipt of the amount, sent by Post-office order or otherwise, as explained in the enclosed printed circular.—I am, Sir, yours faithfully, **FREDERICK ADAIR, M.D.**"

The "enclosed circular" is of the usual abominable description; and, *inter alia*, gives the price, etc., of the different sizes of packages of "The Restorative Mixture."

Now, if the above had been produced in evidence for the prosecution, the Sheriff would, I think, have little difficulty in deciding that, if "Dr." Adair does not "carry on a business as a medical practitioner" (to which, indeed, technical objection might be taken), he assuredly carries on a business which should be designated by a less dignified name.

Now, I must say that I cannot absolve the medical profession from contributing to keep up the extensive ramifications of this cruel form of quackery. On the one hand, there is a mawkish taciturnity, and, on the other (I refer to legitimate practitioners in the legal meaning of the term), a dissemination by means of books of the grossest exaggerations in the aberrant states of the generative system. Dr. Beale observes that "Spermatorrhoea has been defined to be 'all losses of seminal fluid not occurring as the result of sexual intercourse';" and with just indignation denies that there is any such disease according to this definition. I go further than Dr. Beale, perhaps, in maintaining that no *continent* young man between seventeen and thirty-five is healthy unless there be an occasional emission of seminal fluid. I perfectly coincide with Dr. Beale in reproaching the extravagant assertions "that phthisis, cerebral congestion, epilepsy, general paralysis, and insanity," have been proved to stand in the relation of cause and effect in the cases of so-called spermatorrhoea quoted in books. Believing firmly in these opinions, I do not go the length of asserting that what is a normal condition may not in some cases lapse into that which is abnormal, and that cases of spermatic incontinence do not occasionally occur requiring medical treatment. I am at present preparing for publication a small treatise "On the Functional Diseases of the Renal, Urinary, and Reproductive Organs," in which it shall be my endeavour to expose not a little of the extravagant assertions of certain writers.

November 16th, 1871.

I am, etc., **GLASGOWENSIS.**

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

#### DR. PIRRIE ON ACUPRESSURE.

SIR.—I observe in your impression of October 28th, a reply by Dr. Will to my remarks on Dr. Pirrie's recent paper on Acupressure. Had Dr. Will confined himself to answering the question I put, his wisdom would have been evident. As I cannot receive his *ipse dixit* without proof, I must again trouble you in order that the points referred to may be settled.

If Sir J. Y. Simpson used tortoiseshell in 1860, Dr. Pirrie must have been in ignorance of the fact when he called it the Aberdeen method; for he says, even in his last paper, that he was the first to describe it. This statement of Dr. Will's shows that I was not so very far in error in drawing attention to the circumstance. I feel grateful to Dr. Will for mentioning this fact; but as it is only an assertion, and as I am always willing "to extend my information," Dr. Will, perhaps, may supply the proof that Sir J. Y. Simpson was the first to adopt tortoiseshell.

Dr. Will plumes himself with his superior information, and, in the plenitude of his wisdom, dictates from the pinnacle of his hardware experiences; but I fear the profession will not accept the source whence he derives his facts. "Any wire-worker" would scarcely be an acceptable demonstrator to give ocular proof of the *resiliency* of the application of terms in surgery. It has been said that "there is nothing new under the sun"; and it would be foolish in me, therefore, to deny that Dr. Pirrie has discovered some new property of iron-wire, of which he only informs us *en passant*. I have failed to procure elastic and inelastic iron wire; and such men as Wells and Son know it not.

I quite understand what is meant by hard-tempered and by annealed iron-wire—the terms used by most people. Resilience and flexibility are properties of hard-tempered wire; and ductility that of soft. Most elementary school-books will give Dr. Will this information should he be humble enough to learn therefrom. If he be not, he will find an exposition in the more advanced text-books of Natural Philosophy. A substance is elastic when, having been altered in shape by some applied force, it regains its form when this force is withdrawn. India-rubber is a good example of this kind of substance. If you take a piece of iron or iron wire, let it be hard or soft, tempered or annealed, and draw it from its shape, it will not assume the same form *per se* on the withdrawal of the force. Take a piece of hard iron-wire, and bend it—it will resist, because of its inherent flexibility; but it cannot therefore be said that it is elastic; neither can the contradistinctive term inelastic be used to designate a property of iron-wire which it does not possess. In some respects, *resiliency* and *elasticity* are synonymous terms; but the former implies more of a rebounding—the line, but not the form of the substance having been altered; the latter, the resuming of the original shape—both line and form having been altered.

May I be permitted further to remind Dr. Will that he has omitted, perhaps inadvertently, to mention "the otherwise excellent works on surgery" that contain "only absolute truths" of "a new means of arresting surgical hæmorrhage." His communications may not have extended thus far. But in justice to the authors of such works, and in justice to the gentlemen who may present themselves for examination at Aberdeen, prepared from the unreliable text-books of those authors, it is but right that such assertions should be accompanied by the names of the books, especially the editors which are so far behind the times.

Fetterarn, November 11th, 1871. I am, etc., **A. F. McRAB, M.D., C.M.**

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Liverpool Daily Courier, Nov. 29th; The Ipswich Chronicle, Nov. 15th; The Irish Times, Nov. 25th; The Sheffield Daily Telegraph, Nov. 25th; The Midland Counties Express, Nov. 25th; The Bedfordshire Mercury, Nov. 25th; The Lancashire Chronicle, Nov. 24th; New York Tribune, &c.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

#### CAUTION.

Ir having come to the knowledge of the Publisher that circulars have been distributed calculated to mislead advertisers as to the circulation of this journal, he feels it incumbent on him to state that its circulation far exceeds that of any other medical periodical, and that it has for many years past steadily increased, and is still increasing.

**COMMUNICATIONS, LETTERS, &c.**, have been received from:—

Sir J. Ranald Martin, London; Dr. Henry Thompson, London; Dr. Graily Hewitt, London; Mr. James Dixon, London; Mr. G. Greenwood, Blackheath; Dr. J. Warburton Begbie, Edinburgh; Dr. Creighton, Berlin; Mr. Hammond, London; Mr. Churton, Erith; Mr. Southall, Birmingham; An Associate; The Secretary of the Pathological Society; Mr. Bickersteth, Liverpool; Mr. F. H. Hodges, York; Dr. Cortis, London; Mr. F. Grant, Market Harborough; The Secretary of the Clinical Society; Dr. Cecil Tessier, Biddenden; Dr. Alfred Hollis, Dorchester; Dr. Edis, London; Dr. C. Black, Clifton; Dr. J. Matthews Duncan, Edinburgh; Dr. J. H. Carruthers, Manchester; Mr. Kemp, London; Mr. Taylor, Birmingham; Dr. Barham, Truro; Dr. Moore, Dublin; Dr. Arthur Farre, London; Dr. Woodward, Worcester; Dr. Todhunter, Dublin; Mr. De Renzy, Kingstown; Mr. H. Cripps Lawrence, London; Dr. Glover, London; Mr. R. W. Parker, London; Mr. M. C. Soutter, London; Mr. Warrington Haward, London; Surgeon-Major Wyatt, London; Dr. Boyd Mushet, Southgate; Mr. Bartlett, Birmingham; Mr. Higginson, Liverpool; Dr. R. W. Taylor, New York; Dr. Liebreich, London; Dr. Payne, London; Staff-Surgeon Hogg, Woolwich; Mr. Jessop, Leeds; Dr. Neil McGreevy, Drogheda; Mr. William Stokes, Dublin; Mr. Nicholson, London; Dr. C. E. Fitzgerald, Dublin; Mr. Harry Leach, Greenwich; Dr. Wardell, Tunbridge Wells; Mr. Turton, Wolverhampton; Mrs. Trevor-Roper, Rock Ferry, Cheshire; Dr. Corfield, London; Our Liverpool Correspondent; Mr. J. W. Kenyon, Folkeham; Mr. Annandale, Edinburgh; Dr. McRae, Fettercarr; Mr. Tait, Crieff; Mr. Callender, London; Dr. Marcet, Nice; Dr. Bradbury, Cambridge; Dr. Elliott, Hull; Dr. Hughlings Jackson, London; Dr. Bishop, Paris; Dr. Morell Mackenzie, London; The Secretary of the Harveian Society; Dr. Brunton, London; Dr. Shapter, Exeter; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Mr. W. W. Reeves, London; Dr. Playfair, London; Mr. Symonds, Oxford; Dr. Moxon, London; Mr. John W. Langmore, London; Mr. Benson Baker, London; Mr. Holland, London; Mr. Hodgson, Brighton; Dr. Cobbold, London; Dr. Thorowgood, London; Dr. Pitman, London; The Secretary of the Hunterian Society; Dr. Hermann Weber, London; Mr. Berkeley Hill, London; Mr. Bottomley, Huddersfield; Dr. W. Young, Malton; Dr. Ritchie, Edinburgh; Dr. Morell Mackenzie, London; Dr. Spencer Cobbold, London; Dr. Charles Parsons, Dover; Mr. F. H. Edmunds, Rochester; Mr. J. B. Walker, Edinburgh; Mr. Peter Campbell, Bridge of Allan; Dr. Trollope, St. Leonard's; Dr. R. Liveing, London; Mr. Stansfeld, Redland, Bristol; Dr. Foster, Birmingham; Dr. Warwick, Richmond; Inspector-General Murray, London; Mr. E. Norton, London; Mr. Buxton, Liverpool; Dr. Marshall, Windsor; Dr. Bott, Bury; Dr. Davies, Ebbw Vale; Dr. Savage, Alston; Dr. Woodward, Worcester; Dr. J. Harley, London; Mr. Steel, Hampstead; Dr. H. Bennet, Mentone; Mr. C. Casey, Carlou; &c.

#### BOOKS, &c., RECEIVED.

Symptoms and Treatment of Malignant Diarrhoea, better known by the name of Asiatic Cholera, as treated in the Royal Free Hospital during the years 1832, 1833, 1834, 1843, and 1854. By William Marsden, M.D. Fourth Edition. Edited by Alex. Marsden, M.D., F.R.C.S.E. London: 1871.

Anæsthesia, Hospitalism, Hermaproditism, and a proposal to stamp out Small-pox and other Contagious Diseases. By Sir James Y. Simpson, Bart., M.D., D.C.L. Edited by Sir W. G. Simpson, Bart., B.A. Edinburgh: 1871.

On the Treatment of Hyperpyrexia, as illustrated in Acute Articular Rheumatism by means of the External Application of Cold. By Wilson Fox, M.D., F.R.C.P. London and New York: 1871.

On Decapitation as a Mode of Delivery in Cases of Shoulder-Presentation, in which Version cannot be safely effected. By George H. Kidd, M.D., F.R.C.S.I. Dublin: 1871.

Report on the Sanitary Condition of the Parish of St. Mary Abbots, Kensington, during the year 1870. By T. Orme Dudfield, M.D., Medical Officer of Health. London: 1871.

# LECTURES ON THE EXPERIMENTAL INVESTIGATION OF THE ACTION OF MEDICINES.

BY T. LAUDER BRUNTON, M.D., D.Sc.,

Joint Lecturer on Materia Medica, and Casualty Physician, at St. Bartholomew's Hospital; etc.

## IV.—DETERMINATION OF THE EXACT STRUCTURES THROUGH WHICH DRUGS AFFECT THE HEART AND VESSELS.

*Comparison of the Effects of Drugs on different Animals in different Doses.*—Mode of determining the Exact Cause of Symptoms.—Mode of raising Blood-pressure.—Modes of counting the Beats of the Heart.—Causes of Quickened Pulse.—Direct Stimulation of the Sympathetic.—Stimulation of Cardiac Ganglia.—Paralysis of the Vagus-roots and Fibres, and of its ends in the Heart.—Causes of Slow Pulse.—Irritation of Vagus-roots.—Mode of supplying the Head and Body with different kinds of Blood.—Indirect Irritation of Vagus-roots through the Blood-pressure: mode of lowering and raising it.—Reflex Irritation of Vagus-roots.—Indirect Irritation through the Respiration.—Irritation of Vagus-fibres.—Increased Conducting Power of Fibres.—Stimulation of Vagus-ends.—Paralysis of the Sympathetic.—Paralysis of the Cardiac Ganglia.—Part of the Ganglionic Apparatus Affected.—Nervous System in the Heart.—Motor Ganglia.—Stimulating Ganglia.—Inhibitory Ganglia.—Connecting Apparatus.—Action of Drugs on the Inhibitory Apparatus.—Nicotia, Muscaria.—Antagonism of Atropia and Physostigma: bearing of this on Therapeutics.—Paralysis of Co-ordinating Apparatus.—Paralysis of the Muscular Fibres of the Heart.—Blood-pressure: mode of determining whether changes in it are due to alterations in the Heart or Vessels.—Elimination of the Action of the Heart: Division of its Nerves.—Irritation of Vagus.—Ligature of Aorta.—Artificial Circulation: in Mammals, in the Frog.—Observation of Vessels.—Action on Vasomotor Centre; on Vascular Walls.—Influence of the Action of Parts surrounding the Vessels upon them.—Action of the Pulmonary Circulation on the Blood-pressure.—Use of the Sphygmograph.

**COMPARISON OF THE EFFECTS OF DRUGS.**—Before proceeding to examine separately the different structures through which a drug may act on the blood-pressure, it is advisable to compare the effects which it produces on animals of different kinds, such as dogs and rabbits, as well as the action of larger and smaller doses on animals of the same kind. Continuing to take as an example the action of atropia, admirably investigated by Von Bezold, we find the following results.

With a small dose of atropia injected into the jugular vein towards the heart:

The blood-pressure rises in both rabbits and dogs:

The pulse becomes quick, rising in rabbits from 256 to 288; in dogs, from 80 to 240.

With a larger dose:

The blood-pressure, in both rabbits and dogs, falls at first and afterwards rises to the normal.

The pulse becomes quick in both.

With an additional dose:

The blood-pressure in rabbits falls very low as the poison reaches the heart; afterwards rises; and falls again below the normal.

The pulse becomes slower, and then quicker.

With a very large dose:

The blood-pressure sinks instantly in both rabbits and dogs.

The pulse in rabbits becomes slower and weaker, and then stops; in dogs, it becomes quick.

This comparison between the effects which atropia produces in different animals, and in large and small doses in the same animal, shows us that it sometimes raises and sometimes lowers the blood-pressure, but that it always quickens the pulse, except when a large quantity of the poison is introduced at once into the heart of the rabbit. On consulting the table already given (BRITISH MEDICAL JOURNAL, June 3rd, page 583), it will be seen that quickening of the heart may be due to stimulation of the sympathetic, either directly by the drug or indirectly by diminution of the blood-pressure; to stimulation of the cardiac ganglia; or to weakening or paralysis of the vagus. Any one of these conditions may cause quickened pulsation; and, in order to determine which of them really does it, we must test each one of them separately by farther experiment.

**MODE OF DETERMINING THE EXACT CAUSE OF SYMPTOMS.**—The plan which we follow is this: we suppose for the time being that the

cause which we are testing is the true one, and consider what effects it will produce under certain conditions. We then supply these conditions experimentally, and see whether or not the results we obtain correspond with those which we should find if our supposition were correct. So in the present instance we first ask, Is the quickening of the pulse due to indirect stimulation of the sympathetic roots by diminished blood-pressure or not? We suppose for the moment that it really is so, and we consider that if we raise the blood-pressure we shall remove the cause of quickening and bring the pulse down again to its normal rate. We then proceed to raise the pressure, and see whether or not the pulse is rendered slow, as we expect it to be. In the case of atropia, a special experiment is not necessary for this purpose, as we have seen that small doses do not lower but raise the blood-pressure, at the same time that they quicken the pulse; consequently the quickening cannot be due to indirect stimulation of the sympathetic. Other drugs, however, such as nitrite of amyl, even in small doses, lower the blood-pressure at the same time that they quicken the pulse; and in their case we must raise the blood-pressure artificially.

**MODE OF RAISING BLOOD-PRESSURE.**—This may be done either by injecting a sufficient quantity of the defibrinated blood of another animal of the same species, warmed to 98 deg. Fahr., into the carotid or crural artery towards the heart, or by compressing the aorta. The aorta may be either compressed by the thumb of the operator, or by a narrow pad of cork laid over it and pressed upon it by a tourniquet, of which the strap has been passed round the animal's body.

**MODE OF COUNTING THE BEATS OF THE HEART.**—Now, if we wish to determine the blood-pressure at the same time with the pulse-rate, we may count the latter from the oscillations which each beat of the heart produces in the tracing of the kymographion, or from the sphygmoscope attached to it; but this is not always necessary, and we may wish to ascertain the pulse-rate without going to the trouble of opening an artery and using a manometer. We may do this in three ways—1. By feeling the pulse in one of the large arteries, such as the crural, with the finger; 2. By listening to the beats of the heart with a stethoscope; 3. By the motion of a needle stuck into the ventricles. For this purpose a fine harelip-needle is inserted at the point where the apex beats, and is pushed upwards into the substance of the ventricle. At its upper end it may have either a knob, or a loop to which a thread can be attached, and a barb at the point will prevent it from changing its position in the heart when traction is made upon it. In rabbits, the point where the needle should be inserted is in about half an inch to the left of the sternum in the third intercostal space, and the length of the needle used should be about three inches. Various means have been proposed for counting the oscillations more readily than can be done by simply watching the movements of the needle itself. The knob of the needle may be allowed to strike against a wineglass, and the pulsations may thus be counted by the ear; or a needle without a knob may be used, and a rice-straw with a piece of bright-coloured paper attached to it may be slipped over it, so that its vibrations, amplified by the long straw, and made more visible by the bright-coloured paper, may be readily counted by the eye.

A convenient way of registering the oscillations on an upright cylinder is one devised by Professor Stricker. One of Marey's cardiographic levers is fixed on a rod close to the side of the animal and some distance above it, and a small piece of cork attached to the lever. One end of a fine thread is then fastened to the needle, and its other end pulled through a slit in the cork till it is sufficiently tight to make the lever vibrate with each movement of the needle; it is then fastened by twisting it round the lever, or by a little sealing-wax. If the lever be not raised several inches above the needle, it is pulled too much to a side and not sufficiently downwards to give a good tracing. The tracing may be taken either on plain paper with a glass-pen or camel's hair-brush attached to the lever by a piece of cork, or with a dry point on smoked paper. Instead of a vertical cylinder a horizontal one may be used, and is perhaps still better. In this case the lever should be nearly on a level with the needle, and not raised much above it.

**IS THE QUICKENING OF THE PULSE DUE TO DIRECT STIMULATION OF THE SYMPATHETIC?**—If so, the injection of the drug should cause an increase in the pulse-rate after the vagi have been divided as well as when they are intact. We, therefore, divide the vagi, inject the drug into the veins, and see whether or not the pulse-rate is increased. On doing this with atropia it is found that the pulse becomes slower rather than quicker, showing that the drug does not stimulate the quickening nerves of the heart. The increased rapidity of the pulse which it produces when the vagi are intact is, therefore, not due to this cause.

**IS THE QUICKENING DUE TO STIMULATION OF THE CARDIAC GANGLIA?**—The experiment just mentioned shows that it is not, for if it were, injection of atropia should cause quickening after division of the vagi. Supposing, however, that it had caused quickening, the question

whether the acceleration was due to the ganglia or the sympathetic would have to be decided by dividing all the nerves going to the heart with a platinum-wire heated by electricity, and then injecting the drug, or by applying it to the heart of the frog in a way which I shall afterwards describe. If it quickened the beats of a heart thus separated from all other nerves, it could only do so by acting on the cardiac ganglia themselves.

**IS THE QUICKENING DUE TO PARALYSIS OF THE VAGI?**—The exclusion of the other causes leads us to believe that it is due to this; but, in order to avoid the possibility of error, we must try to confirm our conclusion by other experiments; and, moreover, we have still to find out which part of the vagus is affected—its roots, its fibres, or its ends in the heart.

**ARE THE VAGUS-ROOTS PARALYSED BY THE DRUG?**—We are enabled to answer this question by our knowledge of the fact, that poisons only act on the parts to which they are carried by the blood, and that when introduced into the circulation they do not reach every part of the body at once, but are carried on with the blood-stream first to one part and then to another, and will reach a part near the point where they were introduced before one which is farther off. Thus if we inject a drug into the carotid it will be carried direct to the head, and will act on the medulla oblongata and the roots of the vagus before it reaches the heart; but if we inject it into the jugular vein it will reach the heart and act on the vagus-ends in it before it reaches the roots in the medulla. If atropia paralyse the vagus-roots, then its injection into the carotid towards the head should be followed by rapidity of the pulse more quickly than its injection into the jugular; but if it act on the vagus-ends in the heart, the pulse should become rapid more quickly after injection into the jugular vein towards the heart than after injection into the carotid. On testing this experimentally, it is found that, when atropia is injected into the jugular vein towards the heart, the pulse at once becomes quick, even before the injection is finished; but, when it is injected into the carotid towards the head, the pulse is not quickened for a quarter of a minute or more, or, in other words, till the poison has had time to pass through the capillaries of the head and go through the veins to the heart. This, then, shows that it is the vagus-ends in the heart, and not the roots in the medulla, that are paralysed by it.

**ARE THE VAGUS-FIBRES PARALYSED?**—From the rapidity with which paralysis of the vagus occurs after atropia reaches its ends, we have already come to the conclusion that the ends are the part affected rather than the roots or fibres; but it is well to substantiate our conclusion by further experiment. We divide the vagus and galvanise its peripheral extremity. If we do this to a normal vagus, the heart will beat more slowly or stand still altogether; but if either the fibres or ends of the nerve have been paralysed, no change will be produced in the heart's rhythm by the application of galvanism to its trunk, and this we find to be the case after the administration of atropia. But this experiment does not enable us to decide which part of the nerve is paralysed—the fibres or the ends, for in either case the effect would be the same. We may do this, however, by observing the effect which irritation of the vagus-trunk produces on such of its fibres as do not go to the heart. If it were the fibres which were paralysed, we should expect that those which go to the heart would not be the only ones affected, but that those going to other parts would be paralysed likewise.

I have hitherto spoken of the vagus as if it were a simple nerve containing only inhibitory fibres for the heart, but it is really a most complicated bundle, containing centripetal fibres having probably no fewer than eleven different functions, and centrifugal ones having nine or ten; so it is little wonder that it has long been a puzzle to physiologists, and even yet its functions are not completely investigated. Among these fibres are some which produce contraction of the oesophagus and muscles of the larynx; and if we find that irritation of the vagus continues to produce contractions in these parts after it has ceased to render the heart's action slow, as is the case after injection of atropia, we conclude that the fibres are not paralysed. Dr. Rutherford has shown that the best mode of observing the effects of irritation of the vagus on the muscles of the larynx, is to open it in front and place the animal so that the light may be reflected from the inner surface of the arytenoid cartilage, as the slightest movements can then be readily detected. In this way it is found that atropia produces complete paralysis of the cardiac branches of the vagus, while the others are unaffected; and we are forced to conclude that it acts not on the fibres but on the ends of the heart. A more direct method is to apply the drug dissolved in an indifferent fluid, such as half per cent. solution of chloride of sodium, to the vagus itself, and then to irritate the nerve above this point, and see whether the irritation produces its usual effect. This may be done by dropping the solution on the nerve after placing a piece of gutta-percha tissue below it, so as to keep the fluid from reaching the tissue below and being absorbed.

**HOW DOES A DRUG RENDER THE HEART'S ACTION SLOW?**—We have now gone over the experiments which are necessary to determine what the structure is through which a drug quickens the heart's action, and we have now to consider those which we require when investigating the action of one which renders it slow. It may do so by irritating the vagus-roots, fibres, or ends; by increasing their excitability, so that they act more strongly when stimulated; or by paralysing the sympathetic, the cardiac ganglia, or the muscular substance of the heart itself.

**DOES IT ACT BY IRRITATING THE VAGUS-ROOTS?**—In order to answer this question, we divide both vagi and then inject the drug. We thus separate the heart from the vagus-roots and deprive them of any influence over it, so that, if they have been the cause of slowness of the pulse in previous experiments, it will not occur in this; but if the slowness have been due to other causes it will, with one or perhaps two exceptions, be noticed in this experiment just as it would had the vagi been intact. These exceptions, which we will consider afterwards, are increased excitability of the vagus-fibres and ends. The vagus-roots can only act on the heart through the medium of the fibres and ends; if the drug itself should affect these structures, its action on the heart may be much altered or even destroyed. If the vagus-ends be paralysed, the roots can exert no more action on the heart than they can after we have cut through the trunks; and if the excitability of the ends be increased, the power of the roots over the heart will be greatly augmented, so that the heart's action may be made slow without there being any actual irritation either of the roots or ends. In order, then, to find out what effect the drug has on the vagus-roots themselves, we must inject it into the carotid, so that it may reach them before it reaches the fibres or ends; and note what change occurs in the heart-beats immediately after injection. This is the effect of the drug on the roots themselves; and, by comparing it with the pulse-rate a quarter of a minute or so afterwards, when the drug has reached the vagus-ends, we may discover whether their excitability has been increased or diminished. Thus, in the experiment already mentioned for ascertaining whether or not the vagus-roots are paralysed by atropia, we find that, when we inject it into the carotid, we get immediate slowness of the pulse, showing that the vagus-roots are irritated by the drug; but whenever it gets round to the heart it paralyses the vagus-ends, and the slowness at once disappears. If we were to keep the head alive by supplying it with an artificial stream of blood containing atropia, and prevent any of the poisoned blood from reaching the heart, the slowness might be continued indefinitely.

**MODE OF SUPPLYING THE HEAD AND BODY WITH DIFFERENT KINDS OF BLOOD.**—In his researches on respiration, Hering employed a method of this sort, at one time supplying the brain with blood loaded with carbonic acid while the blood of the body was richly arterialised, and at another sending arterial blood to the brain while respiration was stopped and the blood circulating in the body was intensely venous. For this purpose he opened the thorax and tied the left carotid and innominate close to the aorta, and the vena cava superior close to the heart in a cat; he then introduced one cannula into the innominate artery, and another into the vena cava, and injected dog's blood, defibrinated and warmed, into the innominate artery, while he allowed it to flow out by the vein.

In atropia, we have an example of a drug which acts on more than one part at once, and whose action on one part completely neutralises the effect which its action on the other would produce. In the case of others, however, we have the action on the different parts strengthening each other, as in veratria, which, like atropia, stimulates the vagus-roots, but, instead of paralysing the ends, increases their sensibility, and thus greatly augments the effect which the excited roots would have exercised over the heart, even had the ends remained unaltered.

**ARE THE VAGUS-ROOTS IRRITATED DIRECTLY BY THE DRUG OR INDIRECTLY THROUGH INCREASED BLOOD-PRESSURE?**—Along with the slow pulse, produced by the injection of atropia into the carotid, a rise occurs in the blood-pressure; and how are we to determine whether the irritation of the vagus-roots is due to this increase, or to the direct action of the drug itself? This is a question very difficult to solve in the case of atropia, on account of the rapidity with which the vagus-ends are paralysed and all influence of the root over the heart destroyed. In the case of other drugs, however, where time is allowed, the question might be settled by diminishing the blood-pressure and seeing whether or not the slow pulse returned to its normal rate, and then raising it again and observing whether the pulse again became slow.

**MODE OF LOWERING AND RAISING THE BLOOD-PRESSURE.**—The blood-pressure may be lowered by opening a large artery, such as the carotid or crural, and allowing the blood to flow out into a vessel warmed to 98 deg. Fahrenheit, and again raised by injecting the warm blood back into the artery. Or we may adopt Ludwig and Asp's plan, of inserting into the central end of the carotid a straight tube with a

stopcock in its middle, and the moist bladder of a small animal, well emptied of air, tied to its free end. When the stopcock is opened, the blood rushes from the carotid into the bladder, and the tension in the arteries is diminished; but, when we press the blood out of the bladder back into the arteries, the tension on them is again increased.

ARE THE VAGUS-ROOTS IRRITATED REFLEXLY FROM SOME OTHER PART OF THE NERVOUS SYSTEM?—There are two ways of deciding this: the first is to inject the poison in such a manner that it shall reach the vagus-roots before it reaches the other nervous structures through which we suspect it to act reflexly; the second is to remove these nervous structures themselves, or to destroy their function by means of some other poison. Thus, if we think that atropia, when injected into the carotid, acts on the medulla through the cerebrum, we may either remove the latter, or abolish its function by opium or chloral. The application of irritating vapours, such as ammonia or tobacco-smoke, to the nasal mucous membrane of a rabbit, produces still-stand of the heart. We ascertain that this is due to irritation of the vagus by cutting it and finding that the vapour then has no effect; and we next decide that the irritation is conducted to the nervous centres through the trigeminus and not through the olfactory nerve, by observing that section of the former likewise prevents the action of the vapour on the heart, while section of the latter does not affect it.

ARE THE VAGUS-ROOTS IRRITATED INDIRECTLY BY THE DRUG IMPAIRING RESPIRATION, AND THUS ALLOWING CARBONIC ACID TO ACCUMULATE IN THE BLOOD?—In the experiment just mentioned, we have ascertained that the vagus is irritated, and that irritation is conducted to the nerve-centres through the trigeminus, but we do not know that the irritation is directly reflected from the trigeminus to the vagus. It might be due to irritation of the vagus-roots by carbonic acid, which has accumulated in the blood from impeded respiration; for the irritating vapour applied to its nose causes the rabbit to close its nostrils and stop breathing for a while if the trigeminus be intact, but when it is cut no irritating impression can be conveyed to the brain, and so no closure of the nostrils takes place, either voluntarily or reflexly. The rabbit, therefore, continues to breathe freely; no carbonic acid accumulates in the blood, and no irritation of the vagus occurs. Other drugs, such as strychnia and curare, etc., impede respiration—not by causing closure of the nostrils and consequent obstruction to the passage of air to the lungs, but by acting on the muscles and nerves and diminishing the respiratory movements. Strychnia does this by producing tetanic contraction of the respiratory muscles, curare by paralysing them, and chloral by diminishing the excitability of the respiratory nervous centre. In all such cases, in order to ascertain that indirect irritation of the vagus from impeded respiration is not the cause of the slowing of the pulse, we insert a cannula into the trachea and begin artificial respiration; we then note the rate of the pulse and blow the irritating vapour into the nostrils, or inject the drug into the veins, and see whether or not the pulse is rendered slow, taking care to keep up artificial respiration all the time. If the drug cause convulsive movements which interfere with the proper performance of artificial respiration, curare should be given so as to prevent their occurrence, and the experiment should be again repeated.

ARE THE VAGUS-FIBRES IRRITATED?—To ascertain this we apply the drug dissolved in an indifferent fluid, such as a solution of half per cent. of chloride of sodium, or serum, to the nerve, and notice whether any change occur in the heart-beats. Care must be taken that the solution of the drug be not applied in too concentrated a solution, as it might then have an irritant action, which it could not have if it reached the part through the circulation, and false conclusions might thus be arrived at.

IS THEIR CONDUCTING POWER INCREASED, SO THAT THE ROOTS CAN ACT THROUGH THEM ON THE HEART MORE READILY AND POWERFULLY?—If their conducting power be increased, other stimuli as well as those from the roots will act more powerfully on the heart. We therefore divide the vagi and irritate the peripheral end of one or both by means of one of Du Bois Reymond's induction-coils, and note at what distance from the primary coil the secondary one must stand in order to produce stoppage or slowness of the heart; we then apply the drug to the nerve below it and again irritate. If the excitability of the nerve be increased, stoppage or slowness should be produced when the distance between the primary and secondary coils is greater—that is, when the current is weaker than before. It is generally assumed that the fibres are not likely to be affected, and these experiments are rarely performed.

ARE THE VAGUS-ENDS EXCITED?—We may test this in the same way as the action on the roots, by injecting the drug at one time into the jugular and at another into the carotid. If it increase the excitability of the ends without affecting the roots, we should find it produce, when injected into the jugular vein, immediate slowness of the pulse,

which would not be increased in a quarter of a minute afterwards, when the drug had reached the roots. When injected into the carotid, no slowness should occur till sufficient time had elapsed for it to pass round to the heart. If it increase the excitability of both roots and ends, immediate slowness should occur, whether it be injected into the jugular or carotid, and this should become more marked after fifteen or twenty seconds. If, like physostigma, it increase not only the excitability of the vagus-ends, but that of the quickening centre in the head, injection into the jugular should be followed by immediate slowness, which would become less marked when the drug reached the head, and injection into the carotid by an immediate quickening, which would become less or give place to slowness when the drug reached the heart.

At first sight one might think that, after time had been allowed for the drug to pass round the circulation and be applied both to the vagus-roots and ends, its action on the heart would be the same whether it had been originally injected into the jugular or into the carotid; but this is not the case, for that organ towards which the drug was injected gets a larger dose, and its action is more strongly excited than that of the other. Thus when physostigma is injected into the carotid, the quickening centres are stimulated and the pulse-rate rises; and, although the pulse falls somewhat after the vagus-ends have also been acted on, it nevertheless continues above the normal, the stimulation of the vagus-ends not being able to counteract the still more excited quickening centres. When it is injected into the jugular, the vagus-ends get the largest dose; and, although the pulse, which is at first made very slow, may afterwards, become quicker, it does not reach the normal, the quickening centres being unable to counteract the more strongly excited vagus. If the vagus be cut, however, the pulse becomes quicker than it would have done had no physostigma been given; or, if the vagi be first cut and the drug injected, the pulse is quickened at once. One might think that, since the drug acts on the vagus-ends, its action should remain after the nerves themselves have been divided; but since it is by increasing the excitability of the ends that it acts, if we separate these ends from the roots, and thus remove their normal stimulus, their increased excitability can have but little effect. In order to measure the amount of increase, we divide the vagi and irritate them by an induction-coil, noting the strength of current required to produce still stand or slowness of the heart before and after injection of the drug into the veins.

[To be continued.]

#### RUPTURE OF AORTA WITHIN THE PERICARDIUM.\*

AT a recent *post mortem* examination, I obtained the morbid specimen now exhibited; and, as it appears to me of sufficient pathological interest to warrant my bringing it under your observation, I must beg your indulgence for a few moments while I narrate its history. It is a well defined instance of rupture of the aorta within the pericardium. It was procured from the body of a blacksmith, aged 34, who for the last twelve months had been constantly under my notice while at work in his forge, and who, during the whole of that time, was distinguished for energy and skill in his business. About fifteen months before his death, he consulted Dr. Kersey for palpitation and dyspepsia, and was also seen by me; but in spite of frequent and careful auscultation, no morbid cardiac sounds could ever be detected, and a little palliative treatment speedily put him to rights. Since then, if questioned about his health, he always affirmed that he was quite well, except on one occasion a few weeks since, when he complained to me of indigestion, but would not take anything for it.

On the evening of his decease, he worked hard at finishing a job up to seven o'clock, and was in his usual good spirits. He then made a hearty supper, and retired to rest. In less than half an hour, he suddenly exclaimed that he felt choking, and immediately expired. Being soon on the spot, I was able to gather these particulars with precision. A necropsy was made twelve hours subsequently. The body was that of a well nourished man, of medium height, and muscular development. All the thoracic and abdominal contents appeared normal, with the exception of the pericardium, which was much distended, and contained more than two pints of blood separated into liquor sanguinis and crassamentum, the latter very firm and unbroken. The source of this hæmorrhage was a small rent of the ascending portion of the aortic circle on the left side, not larger than a crow-quill. No distinct aneurismal pouch could be found; the rupture, therefore, appears to have been due to the giving way of a small atheromatous spot in the artery.

BENJAMIN BROWNING, Littlebourne.

## ABSTRACT OF A CLINICAL LECTURE ON THE DIAGNOSIS OF URETHRAL AND VESICAL DISEASES.

Delivered at University College Hospital on November 21st, 1871.

By SIR HENRY THOMPSON,

Surgeon to the Hospital.

I COMMENCE to-day my usual course of lectures, modified somewhat by circumstances. Thus I desire to condense a little my opening remarks on diagnosis to-day. I may premise that I give this course of lectures on the diseases of the urinary organs, because my wards offer you so large a field for their study, and also because there is no class of diseases in which you can afford so much relief to the patient as in this, or so certainly mitigate suffering. There are no diseases more painful, and none the relief of which will gain you more gratitude from your patients.

In the matter of diagnosis, however, it is of the greatest importance that it should be a correct one, and not only correct, but rapidly made. I have now to say what I have said to you before, that I interrogate all these patients on the same system, and I advise you to follow this plan. I employ only four questions for urinary patients, and I advise you to use these four questions also, and always in the same order. The first question is, Is there any deviation in the frequency of passing urine? The second is, Is there any pain in the act? The third, Is there any blood in the urine? And the fourth is, Are the characters of the urine altered [quality and quantity]?

We shall see that in all cases of urinary disease these four questions are sufficient, together with the supplementary inquiries which arise out of them; yet we know how often such cases are misunderstood—indeed, the simplest are often mistaken, through not pursuing a systematic method in arriving at a diagnosis. First of all, let us look at the question of frequency. Almost every disease of the urinary organs produces some deviation in the natural frequency of passing urine. As a rule, let it be understood that a man in health does not generally rise at night to pass urine, and that he passes it during the day about five or six times; but when there is any degree of inflammatory action in the mucous membrane of the bladder, however slight, frequency of micturition is induced. Now, how does cystitis produce this increased frequency? When the mucous coat of the bladder is inflamed, it cannot bear to be much extended; and when the bladder contains five or six ounces of urine, or even less, the sensitive mucous membrane suggests that it should be emptied: instead of comfortably containing fifteen or sixteen ounces, it cannot endure the extension, and calls on the muscles to contract without delay. There is one, and one only, of these affections which does not necessarily produce, at first, frequent micturition. I speak of stricture: here it always occurs after a time; but a man may have a considerable amount of stricture for years before he is troubled in the way referred to. Calculous disease produces cystitis, and thus causes an increased frequency in passing urine. Now, as a supplementary question, you should next ask, Is the frequency greatest at night or in the day? If a man have calculus in the bladder, he is not so much disturbed at night, but in the day he is frequently micturating—all movements make him do so. Now, that extremely common complaint, *hypertrophy of the prostate*, is worse at night than by day, as far as frequency of passing urine is concerned. Hence, if a man of about sixty years of age says that he has but recently had urinary troubles, and these are greatest by night, the case is almost made out; you may be sure that a very little further inquiry will demonstrate the fact that he is the subject of hypertrophied prostate.

I come to the second question of *pain*. This question is of greater significance. Suppose the patient says he feels pain. Where do you feel pain—low down in the belly? Then there is almost certainly chronic cystitis. Suppose he says that his pain is in the penis or perineum, you must ask if he feels the pain before, during, or after, passing urine. If the pain be before, that is because the mucous membrane is becoming uneasy in consequence of distension. If he find it painful during or after passing urine, and in the end of the penis, he is likely to have stone; and especially, also, if the pain be increased by exercise. The pain is at the end of the penis in stone. It is almost pathognomonic of calculus to find the pain near to the end of the penis during and after micturition. In chronic prostatitis, the pain is also at the end of the penis. This simulates calculus in the bladder more than any other disease.

The third question is, Has blood passed? This brings us nearer still to the point. Blood may be seen in cystitis, but very rarely. The mode and the circumstances in which the blood has passed, however, determine the nature of the disease. An elderly man, who passes blood in-

timately mixed with the urine, dark in colour, and not altered much by circumstances, with frequent rather than painful micturition, has probably hypertrophy of the prostate. In calculus of the bladder you find blood: it is as common in calculus as hæmoptysis is in phthisis. Then a calculus patient will find blood in the urine after a drive or a ride, or after hunting, and none if he keep quiet; or he may pass a drop or two with the last expulsive effort at micturition, and with pain at the time. Such urine is usually rather florid in tint, while, generally speaking, blood passed from the kidney remains long in the bladder, and, from contact with the urine, becomes brown in colour—it is like porter. This, also, may happen when the bleeding is due to hypertrophy of the prostate.

Lastly, Is the character of the urine perceptibly changed? A man will often tell you his urine is thick; but he does not discriminate between the thickness of pus or mucus, and that from deposited salts, as lithates. Patients are generally very much disturbed unnecessarily on account of thick urine. In this cold weather, the urine, on cooling, deposits its lithates readily, where none would be seen in summer; and you may tell him that, if he apply a little heat to it, he can see for himself that it will become quite clear again, which is never the case if the thickness be due to organic matters like pus or mucus; and if this be not an habitual appearance, you may make light of it. If, on the other hand, a heavy deposit of lithates be constant, you must look into his habits and correct his digestion—probably restrict some indulgence in diet. If, also, the urine do not become clear with heat, you have an organic compound to deal with, and you must find out carefully the source of it.

Let me advise you always to make your patient pass his urine into two vessels for examination. I should not thank you for an examination of urine passed into one vessel; for whatever a man may happen to have lying in the urethra—a passage which is by no means always clear and sound—passes with it. Let him pass an ounce or two into one vessel, and examine only what you find in the second vessel. If there be gleet discharge, if there be stricture of the urethra, you will find shreds of pus and mucus and blood-corpuscles in the first glass, but not in the second. In chronic prostatitis, always in hypertrophy of the prostate, sometimes there will be a deposit in the first vessel, which would much mislead you if you imagined it to come from the bladder or kidney. This specimen you must examine for albumen, for sugar, and you must inquire also the quantity passed *per diem*. Well, then, if a patient have told you that he has frequency of passing urine, increased by exercise; that he has pain at the end of the penis; that he passes blood; and that his urine is changed, you may arrive at a pretty good diagnosis of his case. But you would be very much to blame if you did not further examine the man: you must pass an instrument. It is best to be straightforward with patients and tell them so. People have too much common sense to be dealt with otherwise than plainly in these matters. You need not always sound a man with a stiff rigid metallic instrument at first, who has never had an instrument of any kind in his urethra. It is best to take a soft instrument, pass it gently into the bladder, which produces very little discomfort, and so diminish the patient's fear. You can then say, pass another instrument (which will give you a little more pain), and ascertain completely what is the matter.

[Sir Henry Thompson then exhibited the various instruments used in the diagnosis of diseases of the bladder and urethra, and explained their several uses—promising to continue the subject on the next occasion of his lecture.]

## THE ANTISEPTIC TREATMENT OF WOUNDS.\*

By WILLIAM NEWMAN, M.D. LOND., F.R.C.S. ENG.,

Surgeon to the Stamford Infirmary.

You will all, doubtless, have seen the scattered notices in the medical journals of the "Antiseptic Treatment of Wounds"; and many of you will have read with much interest the admirable Address in Surgery given by Mr. Lister at the annual meeting of our Association in August last. To this novel mode of dealing with wounds I would invite your close attention, convinced as I am that the results, so to be obtained, far outweigh any of the usual sequences of the more ordinary surgical dressings—whether they be looked at from the ready and successful response to the surgeon's art, or from the safety and comfort so ensured to the anxious patient.

My short summer holiday this year was spent in Edinburgh; and

\* Read before the South Midland Branch of the British Medical Association, October 10th, 1871; and before the Shropshire Scientific Branch of the British Medical Association, October 27th, 1871.

to the kind courtesy of Mr. Lister I owe the opportunities of close observation of his treatment in many and severe cases in his hospital practice. On the lessons there learned I have been my subsequent surgical work, and on them, too, as a foundation, I venture to speak to-day, bringing forward some few cases which have been under my own care, and describing, as clearly as I may, the modes of dressing which are employed. Throughout I am but the humble exponent of the views of a most able surgeon, and my only merit is that of having seen what I attempt to paint.

"Segnius irritant animos demissa per aures,  
Quam quæ sunt oculis subjecta fidelibus."

Whether the so-called germ-theory of disease be or be not correct, is no part of my purpose to inquire; the process would be simply wearisome and ill-managed. The only postulate I ask you constantly to bear in mind is that, for the successful dealing with wounds on antiseptic principles, it is imperative thoroughly to *exclude the external atmosphere as such*; and a most rigid obedience to this requirement can alone command the desired success, whether the air be *per se* a toxic agent, or whether it be dust-carrying, and so but a vehicle of those impurities which determine the occurrence of suppuration in an open wound. It is imperative, in other words, that the air in contact with the exposed portions of a wound shall be fully charged with some convenient disinfectant: so charged, it may be admitted to wound or cavity without risk to the patient or anxiety to the surgeon.

Taking, then, the simple case of an ordinary abscess, in which immediate incision is needed, the antiseptic treatment must be carried out as follows. 1. Destroy any putrefactive material about the integument of the part by washing it thoroughly with a lotion of carbolic acid (one part of the acid in twenty of water). 2. A constant cloud of fine spray must be kept up by an assistant, so managed that the hands of the operator and the part to be incised are always enveloped in the spray: one or more of Richardson's spray-producers may be needed for this purpose. The carbolic acid solution for the spray will be sufficiently strong if made of one part of the acid to a hundred of water. 3. The knife employed must first be dipped in carbolised olive oil (one part of the acid to ten of olive oil). 4. The incision being made, the abscess-cavity may, as far as possible, be emptied by gentle pressure. If any vessel should have been divided and need a ligature, it should be tied with some prepared carbolised catgut, and both ends of the ligature be cut off short. 5. The wound may thus be dressed: A piece of "protective" oiled silk, coated with copal varnish, and then covered with a layer of dextrine, so as to retain a little of carbolic acid lotion (one part to forty of water) on its surface—cut not much larger than wound—should be dipped in the lotion just named and then applied; on this a pad of the antiseptic gauze\* must be placed, large enough to overlap thoroughly the wound, and not less than eight layers in thickness. Between the seventh and eighth layers, or those most distant from the patient's surface, must be placed a single layer of macintosh cloth, so as to prevent direct soaking of any discharge through the gauze-covering, and to insure that any moisture which may be poured out shall pass through many antiseptic layers and over some wide space before it can possibly be exposed to the impure influences of a septic atmosphere. 6. For the retention of this covering in place, a strip of the above-named muslin (cut to the width of, and rolled up as, an ordinary bandage) may be applied. The slightly adhesive character given to the muslin will make the requisite turns fit very easily, and be less liable to displacement, than the common calico roller. 7. If it be necessary to wait for some little matter—to replenish the bottle of the spray-producer with the lotion, to change the assistant, etc.—the wound should be covered with a piece of rag, dipped in lotion, containing one part of acid in forty of water. This, for convenience, is known as "a guard". 8. Subsequent dressings—first every day, then at longer intervals—must always be managed in the same way. The spray will need to be unremittently kept up; the fingers to be soaked in the lotion or wetted with the spray; all adhering discharge carefully washed away; and the protective outside pad and bandage applied as before. 9. To small operations, removal of tumours, etc., the above process is thoroughly applicable. If the wound made be deep or tortuous, a tent of lint—a narrow strip—dipped in carbolised olive oil (one part of the acid to ten of oil) must be introduced before the sutures are inserted. At the end of twelve or twenty-four hours this tent may be removed; it will have absorbed the serum oozing from the deeper part of the wound, and so have prevented distension of the deeper parts, and possible formation of pus. 10. In larger operations—e.g., amputations—a larger volume of spray must be secured from two or more of the usual spray-producers, or from the apparatus employed by Mr. Lister. [A new spray-pro-

ducer, which seems likely to be very effective, has just been sent to me by Mr. Gardner, surgical instrument maker, South Bridge, Edinburgh.] Sponges should, before using, be dipped in carbolic acid lotion (one to a hundred): when soiled, they must be washed, first in clean water, then in a lotion of one to forty; and then, just before using, in a lotion of one to a hundred. 11. The following cautions may not be out of place. *a.* The lotions for spray-producers need very careful filtration before being used. It is exceedingly easy to choke the fine apertures through which the spray is delivered. *b.* Hold the muslin-padding closely down over the wound until the layers of bandages shall have retained it closely in place; and leave no channel by which septic air may reach the wound, unprotected by several layers of gauze-bandage. If dressings be loose or displaced, air will soon reach the surface of the wound, and in twelve hours suppuration will be established. *c.* Redress so soon as any trace of stain shall have shown itself at the outer edge of the gauze covering. *d.* Sinuses and wounds opening into mucous canals are ill-filled for thorough antiseptic treatment.

The advantages may be briefly summed up:—1. The dressing is clean, almost inodorous, and singularly painless. 2. The formation of pus as a consequence of the injury, surgical or accidental, is, with due care, prevented. 3. Erysipelas and pyæmia, if not absolutely extinguished, are very rarely seen. 4. The wounds are free from local irritation; no swelling of incised integument and no local redness are to be noticed. 5. There is no constitutional disturbance (traumatic fever) after even severe operations. The dressings are infrequent, and in themselves free from irritating material. 6. The wounds heal rapidly.

CASES.—I. *Abscess in Leg*.—T. W., aged 10, was admitted July 18th, 1871, with a large abscess in the calf of the right leg. An incision was made under the spray, and antiseptic dressing was employed. No pus was discharged after the first day. The blood-clot filled up the incision, and soon became organised. On July 25th, he was discharged cured, having been a week under treatment.

II. *Abscess in Breast*.—E. T., aged 17, was admitted September 12th, with an acute and large abscess in the right breast. An incision was made September 13th under spray; the dressing was as above. No pus was discharged after the first three days. On September 26th, she was discharged cured, the breast being quite well.

III. *Large Chronic Abscess*.—J. W. aged 17, was admitted September 12th, 1871. She was the subject of old hip-joint disease on the left side. The limb was shortened an inch or more, and the femur was dislocated upwards and backwards on the dorsum ilii. There was a large fluctuating swelling on the left thigh, fully six inches long by four broad, reaching upwards nearly to the trochanter, downwards below the middle of the thigh. It was first noticed six months previously. On September 13th, chloroform was given, and I made a free incision into the swelling on antiseptic principles, letting out thirty ounces of fairly healthy pus, with shreds of areolar tissue. No constitutional disturbance followed. The girl became free from pain, and could at once eat and sleep. Subsequent dressings were applied about every two or three days. Now from an ounce to two ounces of pus are discharged at each dressing. The shreds of tissue are no longer to be noticed. Within the last week some small fragments of carious bone have come away, so the abscess is most probably connected with the old bone-disease.

IV. *Large Abscess in Lumbar Region over Right Kidney*.—W. J., aged 38, was admitted October 5th. He was much emaciated, and could not stand upright. He had a swelling in the right lumbar region nearly of the size of a small foetal head. Pulse 120; temperature 103 deg. He had hectic fever, much sweating, and loss of appetite. On October 6th, under chloroform, I incised the swelling, evacuating nearly thirty ounces of pus. The dressing was applied as above described. Pulse 96; temperature 98.4. The hectic never returned, and the man is much better. The back is dressed every two or three days, and about an ounce of pus is discharged. I have had occasion (October 15th) to open also for him a large abscess in the perineum, due, it would seem, to the urethra giving way behind a tight stricture; but this wound, through which some urine filters, could not be subjected to antiseptic dressing.

V. *Compound Fracture of Left Tibia*.—M., aged 12, sustained a severe compound fracture of the left tibia in the upper third on September 16th, 1871. On September 18th, I saw him in consultation. Two inches of the tibia were denuded, and there was a deep wound into the calf separating the muscles from the posterior surface of the bone. The wound was filled with blood-clot, which was just beginning to become offensive. I injected some carbolic lotion (one in twenty) beneath and into the substance of the clot. The limb having been securely fastened on a side-splint, the usual antiseptic dressing was applied. A fortnight later, I heard that the boy was doing very well. There was no pus-formation to be seen; no putrefaction; the blood-clot was becoming organised.

\* For detailed description of this gauze, see BRITISH MEDICAL JOURNAL, January 14th, 1871, page 31. It is supplied by Messrs. Macfarlane, chemists, South Bridge, Edinburgh.

**VIII. Fracture of Right Leg at the junction of Middle and Lower Thirds: Severe Transverse Wound two inches above the Ankle down and into the Tibia.**—W. M., aged 54, was admitted September 8th, 1871. He was thrown down this morning at 8 o'clock, when at work with a reaping-machine. The right leg was seriously injured. When he was seen at 2 P.M., there was found to be a simple fracture of the tibia at the junction of the middle and lower thirds. There was a wound about two inches above the ankle-joint, gaping widely; all the tendons, etc., were divided down to the bone, and the knife of the reaper had made a groove into the tibia itself. He had lost a good deal of blood. The limb was much swollen. The two points of injury, doubtless, communicated. There was hardly an inch and a half of clear skin space between them, and pressure above the fracture made blood well up from the wound below. The leg was put up in a swing splint; the skin was washed, and the wound mopped out with carbolic lotion (one to twenty), and a tent of carbolised oiled lint was introduced to the deepest part of the wound. The tent was removed in twenty-four hours. There was large oozing of blood-stained serum on the dressings throughout the first eight or ten days. The man had had no constitutional disturbance. He had eaten meat since the day after admission. He needed no sedative, and had very little pain. On October 4th, from some want of care in the dressing, and the consequent admission of air, a few drops of pus were noticed for the first time, and small suppuration (never more than half a drachm in two days) afterwards continued. On October 23rd, the wound was all but well; the fracture was sound. He was ordered to have a starched bandage applied.

**IX. Incision into Knee-Joint.**—G. B., aged 23, was admitted August 11th, 1871. He had disease of the right knee-joint of fifteen months' standing. Since an accidental slip the symptoms had been much aggravated. The joint was much swollen, and he could not bear the slightest movement; there was also much pain on pressure. The limb had been confined at home by a long splint, and a weight, working over a pulley, attached to the foot; but these measures had given very small relief. Destruction of cartilage was, no doubt, going on. On August 11th, chloroform being given, I made a free incision on the inner side and parallel to the right patella, letting out at once about a tablespoonful of sero-purulent fluid. Antiseptic dressing was applied. The interrupted splint and pulley was reapplied. The relief was immediate; the man was at once able to eat and sleep. No constitutional disturbance followed. The joint soon became smaller. The blood-clot, which ultimately became organised, filled up the incision, and through the intestines of this clot for ten days or more pus slowly oozed. On September 12th, the wound, which had not been dressed for the past eight days, was now quite well. On October 5th, a starched bandage and pasteboard support was ordered to be applied to the limb. The patient was allowed to move about on crutches. On the 20th, he could bear some little weight on the limb, and was in very fair health.

**XI. Incision into Knee-Joint.**—R. F., aged 17, was admitted September 19th, 1871. She had had for some long time weakness in the left knee. Pain and swelling about the joint came on six weeks before admission, since which time she had kept her bed. On admission, the left knee was much swollen; fluctuation was perceptible; she shrieked on the slightest movement. She had lost flesh; had no appetite; and could only sleep with large doses of opium. On September 23rd, Mr. Eddowes made an incision on the inner side of the patella, letting out sero-purulent fluid mixed with blood. The patient was under chloroform. Considerable relief followed. In two or three days the appetite was much improved. There was no constitutional disturbance; no redness around the wound; no pus from the wound. On October 3rd, the joint was much diminished in size.

**XII. Ovariectomy.**—S. A., aged 32, the subject of marked ovarian disease, was tapped in July 1871, when thirteen pints of fluid were removed—a solid mass remaining in the left iliac fossa. On September 21st, ovariectomy was performed. Carbolic acid spray was employed, and antiseptic dressing. The pedicle, which was thin, was tied in two halves with catgut, and returned. On the 30th, it was necessary to break up the adhesion of the lower part of the wound to relieve the distension from contained fluid. There was a large effusion of blood into the lower third of the abdominal cavity. No putrefaction, however, occurred, and no pus formation until a month after the operation; then it was superficial, from accidental displacement of the dressings. The woman is steadily recovering.

**REMARKS.**—The two cases of acute abscess call for little remark: one was quite well in a week; the other in a fortnight, from date of incision. The cases of chronic abscess have exhibited no sign of constitutional irritation since the evacuation of the contained matter. Both have been much relieved by the procedure; and, as yet, without the risk and dangers which not uncommonly follow the emptying of large

collections of matter. Both instances of compound fracture were so severe that a few months ago I might justifiably have thought of an immediate amputation. In not one particular has there been in either case a trace of uneasiness either to patient or surgeon. The power of making incisions into large articulations, without even a fear of after trouble, is of no small interest; and one, if not both, of these patients will probably owe their limbs to the antiseptic dressing. More than once have I seen amputation through the thigh for less marked states of joint-disease. In the ovarian case, I claim nothing more than the prevention of putrefaction, in the large quantity of blood effused into the peritoneal cavity, by the dressing employed. And, too, so far as one single case may be a precedent, this shows also that the spray of carbolic acid (one to a hundred) does not irritate even the sensitive lining of the abdominal cavity. Other cases might well have been added to the list; but I have chosen these as marked instances of surgical procedure, of not infrequent occurrence, and, I might truly add, not uncommonly followed by tedious recovery or by serious after-trouble when the more usual surgical dressings are employed.

## ON A REGULATED TEMPERATURE IN THE TREATMENT OF DISEASE, ETC.\*

By ALEXANDER ROBERTSON, M.D.,

Physician to the Town's Hospital and City Parochial Asylum, Glasgow.

**GENERAL REMARKS.**—The conclusions deducible from these observations regarding the physiological and therapeutical effects of maintaining a high uniform temperature in such diseases are the following.

1. The results are similar in kind, though differing in degree, with all the modes of application; but, upon the whole, they are more decided and satisfactory with the combined poultice and bag than with either of the others.

2. An uniform high temperature has a powerful general action on the system. But the most striking influence is exerted on the skin, free perspiration usually occurring within half an hour after the agents have been applied, and in some cases continuing for some hours afterwards.

3. In a considerable degree, as a consequent of perspiration, there is a reduction of the general temperature. This, however, is not constant; but where an increase is associated with perspiration it is not great, and does not exceed 0.2 or 0.4 deg. Should there be no perspiration, the general temperature is occasionally increased as much as a degree.

4. As a rule, the high temperature does not excite the heart, but appears rather to have a tonic effect on that organ; for in the majority of the patients there was a reduction in the number of pulse-beats per minute, and it was also generally fuller in volume. Occasionally, however, where perspiration did not appear, there was some, though not a great, increase in the action of the heart; but it is also to be observed that, when sweating was excessive, an enfeeblement of cardiac power was the result.

5. A reduction in the respirations usually occurs when these are abnormally frequent. When, however, there is no perspiration, there may be an increase in the number, but only to a slight extent.

6. According to the testimony of the patients, pain and oppression in the chest are usually relieved, and sometimes entirely removed, and a general feeling of relief is experienced. This remark applies not only to the ordinary bronchial affections, but also to those exacerbations of phthisis pulmonalis in which oppression of breathing is associated with a suppression of perspiration; for relief in that condition was obtained in the cases observed by a restoration of the cutaneous discharge.

7. Perspiration is induced in many cases of renal disease with dropsy, with consequent advantage to the sufferers, and afterwards diuresis may be more free.

8. The application of an uniform high temperature is useful in such disorders as lumbago; the pain in one of the two cases treated being entirely removed, and in the other considerably alleviated, immediately after the application.

9. Its local action on the sensory nerves is not unduly great; for, unless the heat be raised to an unnecessary height, the different media through which it is applied are not complained of by the patients.

10. Its local effect as a counterirritant, so far as is indicated by the vascularity of the integument, is considerable, and may even be so increased as to produce vesication of the surface.

With respect to the results which followed the renewal of the water every half hour during two hours—none of the applications being meanwhile removed—I have only to remark that, as they were very similar

to those which warranted the above deductions, like conclusions may be predicated of them. The chief difference was, that the effects were obtained after a longer time—free perspiration in many cases not occurring before an hour and a half.

It is evident from the numerous observations here recorded, that the heat of a poultice can be maintained during any period desired, at from 110 to 115 deg., and that of a fomentation from 115 to 120 deg.; and these temperatures are as high as can be borne by the patients when continued for one or more hours. It is also proved that, when the water is only changed at intervals of half an hour, the temperature of the poultice may be restored to from 121 to 125 deg., and that of the fomentation to from 126 to 130 deg., by pouring into the bag water at 180 deg.

The beneficial effects of these applications, so far as could be observed, were more decided than those which resulted from the mustard or mustard-and-linseed-poultice in the same class of diseases. Their respective actions, I need scarcely say, are to a great extent different. Locally, mustard acts chiefly as a counterirritant; but, as we have seen, it produces pain, and, in children especially, excites the heart's action considerably. On the other hand, a continued high temperature, besides being, to a certain extent, a counterirritant, exercises a more powerful general influence, as is manifest from its stimulating effect on the leading function of the skin. The combination of the linseed with the mustard, no doubt, during the short time the extra heat is retained, produces the combined effects of an elevated temperature with counter-irritation, but the latter action preponderates. The difference between the effects of the two applications—namely, the continued uniform heat and the poultice of mustard and linseed—was well brought out in the observations on the healthy boy, which I have already detailed at length. Besides the specified diseases, there are many others in which there seems reasonable prospect of advantage being derived from these new applications. For instance, inflammatory affections of the abdominal viscera, many of the inflammations which fall more particularly under the care of the surgeon, and local cutaneous eruptions, particularly when they are little dependent on a constitutional vice.

Should Dr. G. Johnson's theory of cholera—that there is a spasm of the pulmonary capillaries—be sound (it has lately obtained the high sanction of Sir Thomas Watson), then we might anticipate that benefit would be derived from the maintenance of a uniform elevated temperature over the lungs. Whether or not this should prove to be the case, there seems at all events a cordial concurrence in acknowledging the advantages of hot applications to the abdomen.

By means of this bag, with or without moisture, we have the power of applying and maintaining heat as high as can be possibly endured, and for as long a period as is desirable, without disturbing the patient; and were this all it accomplished, it is surely a boon of some moment in a disease usually accompanied by so much suffering.

Another group of diseases of a different kind, in which the application of this principle of treatment promises to be of no small service, are those attended with hyperpyrexia. At the outset, reference was made to the very striking effects of the cold bath in that condition. As has been stated, water of any temperature between the boiling and the freezing points may be circulated through the apparatus, so that in the use of iced water we have a powerful agent for reducing febrile heat. It certainly cannot be so active as the bath; but after the latter it may suffice to maintain the reduced temperature so induced. In cases of medium severity, it may of itself be competent to lower the heat to a point compatible with the safety of the patient. It is assuredly a much less formidable and a more comfortable and convenient means of treatment, and one whose effect is more easily regulated than the cold bath. I regret that no opportunity has as yet presented itself in my experience for testing its power over the febrile state.

I have only further to remark, in reference to the chest-bag, that the calibre of the tubing of which it is made is such that, when it is sufficiently distended, it contains about eight ounces of water, and that the material and coverings are light, so that the combined weight of the bag and contents is less than that of an average poultice. In order to test this point, which is one of practical importance, I caused an experienced nurse to make three linseed-poultices, without instructions regarding the quantity of the meal, but in other respects to be as follows; viz., to be spread on ordinary cotton cloth 8½ by 9½ inches, and to have muslin on its other surface; the whole to be covered with thin waterproof sheeting about an inch wider than the poultice. So prepared, the entire weight of each poultice and its coverings was 16½ oz., 17 oz., and 20 oz. respectively—average, about 18 oz. On the other hand, the weight of the bag, when sufficiently distended with water, is about 12 oz.

Regarding its durability, it is sufficient to state that I have used the same bag in all these observations, which extend over several months, and it is still as serviceable as at first.

We now turn to the uterine bag. Hitherto no means have existed for directly fomenting or applying a low temperature to the neck of the uterus otherwise than by injecting water into the vagina; and we all know that in many cases this method is very inconvenient and of doubtful advantage. Both these ends can be accomplished through the instrumentality of this bag, with comparatively slight disturbance of the patient.

My observations have all been made with the bag alone—that is, without covering of wet lint or other material. The reason of that is, that the idea of attaching loops to it, by means of which a moisture might be applied, only occurred to me quite recently. But though I have not

Fig. 2.—Section of Uterine Bag.

a. Inlet; b. Outlet pipe: outlet one has tap at end. c. Loops for attaching covering of lint. d. Pouch for director to assist insertion.

used it otherwise than uncovered in the treatment of disease, I introduced it in one case with wet lint, first on one surface and then on both, and satisfied myself that in either way it worked quite satisfactorily. Of course, when both surfaces are covered, its introduction is not quite so easy as when only the smooth bag is in contact with the vagina. I need scarcely point out that the lint may be soaked with various medicated solutions.

The cases in which I have had opportunity or leisure to observe its effects are but few, and I will therefore briefly describe them individually.

CASE I.—C. M., aged 53, was suffering from chronic inflammation of the uterus with hypertrophy, remaining after the removal of a fibrous polypus about a year previously. She had endured pain for months in the uterine region, especially at night, and was unable to follow her employment. The bag was introduced and pushed well up behind the neck of the womb; and water on two occasions at 120 deg., and at others it was 110, circulated through it. Within half an hour from the commencement, free perspiration generally occurred. The application was made in the evening and was continued one, two, and sometimes three, hours, for six times in all. The patient stated that on each occasion the pain was relieved, and sometimes temporarily removed altogether, and that she usually obtained refreshing sleep for some hours afterwards, to which she had been previously a stranger. The alleviation of all the symptoms continued, and she shortly afterwards undertook the post of nurse, which she at present holds.

CASE II.—The patient, aged 35, had cancer of the uterus in the ulcerative stage, and was suffering severe pain. Warm water, at a temperature regulated by the patient's feelings, was circulated for two hours on each of two occasions. The day following each application, she stated that she had been soothed by it; that the heat was very comfortable and allayed the pain; that, especially after one of the applications, she had a very good night, sleeping several hours continuously, and that throughout the morning she had none of the sickness and backache which was customary in her experience.

CASE III.—M. M., aged 50, had malignant disease of the uterine neck with deep excavations. A current of hot water, as warm as she could bear it, was circulated for about an hour. At the close, she stated that she had felt the application very comfortable, and, next day, said that she had spent an unusually good night, and was easier.

CASE IV.—J. M., aged 43, had cauliflower cancer of the uterus, and

was subject to hæmorrhage, lasting often about a week, at the menstrual period. The ordinary astringent measures, internal and external, had been carried out on each successive occasion, but often with very little benefit. In this case, cold water has been circulated continuously five different times, for periods varying from half an hour to six hours, with the result of always checking the bleeding at the time. Twice, however, oozing returned after two or three hours, but at other times it did not recur for several weeks.

CASE V.—Martha Q. had hæmorrhage recurring at uncertain intervals, and lasting for a week, and occasionally nearly a fortnight; the exact cause could not be ascertained by a careful examination of the uterus and ovaries. Remedies, local and general, having failed, I circulated cold water for an hour, with the effect of at once stopping the bleeding. Next day it recurred, but again ceased immediately after the use of the bag. This time, however, it soon returned, and I thought it advisable to plug the vagina with sponge soaked in glycerine with tannic acid. On the removal of the plug, it reappeared once more, but gradually passed away.

CASE VI.—Mary M., aged 40, had disease of the right ovary of many years' duration, attended with much loss of blood at the menstrual periods throughout the last two years; and for several months the discharge had never been entirely away. Cold water was circulated in this case for five hours. Bleeding had entirely ceased when the bag was removed, and did not return till two days afterwards, and then only to a slight extent. The patient said that it was "decidedly less" than previous to the use of the bag. She now left the Hospital.

These are all the cases in which I have used this instrument. In the patient Martha Q., the plug on one occasion was apparently more successful in restraining hæmorrhage. But plugging, as is well known, is sometimes followed by dangerous symptoms. I had an illustration of that in the patient H. M. On the last recurrence of the bleeding, the bag not being in my possession at the time, I plugged by the means described in Q.'s case; but afterwards she had severe shiverings, vomiting, and great prostration, which I attributed, at least partially, to the absorption of some of the decomposed blood retained by the plug. No unpleasant effect in any case has followed the use of the bag.

Besides its beneficial action in such cases as I have described, I am hopeful that this apparatus, or other forms constructed on the same principle, may be found to be of service in gradually overcoming some cases of organic stricture, not only of the vagina, but of other passages also. Its distending power is considerable, and might be increased by employing a longer and wider inlet-pipe. In cases of vaginismus, it seems likely to be useful.

Respecting its application: When the object is to stop bleeding, the vessel containing water is raised about two feet above the level of the patient's body, so that, the bag being fully distended, the combined action of pressure and cold is exerted internally. Should we seek to soothe a painful inflamed uterus, no pressure being desirable, the vessel is elevated only a few inches, so far, in fact, as will maintain the circulation of the water.

With respect to the other apparatus, I regret that as yet I have had no leisure to test them in the treatment of disease, except in two cases, which were only imperfectly observed. I have, however, satisfied myself that they work correctly, and are applicable to the objects for which they were designed. A few remarks are called for to indicate the disorders in which they may probably be found useful.

1. *The Spinal Bag.*—Besides its evident suitability for the treatment of ordinary painful and inflammatory affections of the spinal cord and spine, the action of a regulated high or low, or alternately high and low temperature, in such diseases as tetanus, tetany, locomotor ataxy, etc., is worthy of ascertaining. Should it be possible to affect the condition of the sympathetic by cold applications over its course, it may be conveniently done by circulating ice-water through this instrument. I have applied it in a case of slight inflammation of the cord from injury, circulating hot water for an hour. The patient was certainly relieved next day; but to what extent the improvement was due to the continued high temperature it was impossible to determine, as she was receiving other treatment at the same time.

2. *Head Bag.*—I was particularly anxious to have a suitable apparatus for the treatment of diseases of the brain, inclusive of insanity, and have devoted much thought and time to its construction. I have long been of opinion that there was considerable probability of benefit being derived from tepid or warm applications in certain forms of cerebral disorder. It is accepted as a pathological doctrine that there are two opposite states of the blood-vessels of the brain—one of anæmia, another of hyperæmia; so we might anticipate that opposite modes of treatment would probably be of service in conditions so dissimilar. And yet how seldom do we hear of heat being applied to the scalp, by any medium, in affections of the encephalon. Struck by this anomaly,

about two years ago, I prescribed warm fomentations to the head in a case of acute insanity. There did not, however, appear to be any material improvement through their action in that case. On thinking over the subject afterwards, it seemed to me that the temperature was too high, being probably from 130 to 140 deg., and had proved exciting rather than soothing to the brain. Although the results were not encouraging, my belief in the soundness of the principle was not shaken. But I felt that it was impossible to apply it with that degree of exactness which is requisite in the use of so powerful an agent, by such means as I had employed, or were then in existence. By this cap, the difficulty is entirely obviated, as any degree of temperature may be maintained as long as is desired. With respect to cold, also, it is, I think, in all respects a far more convenient and suitable apparatus for its application than the ice-bag, as ice-water may be circulated through it even when the head is resting on the pillow. I would, however, remark that it is very doubtful if real benefit is obtained by the application of a temperature so low as that of ice during a considerable period. The after-effect of a large reduction of heat in a part of the body, or in the system generally, is a reaction to a higher degree than previously to the action of the agent on which the reduction depended. This is illustrated locally in congelation of the skin by ether, and generally by the bath of very cold water. Greater permanent improvement is likely to be secured by a more moderate and prolonged reduction of temperature; and this may be effected by means of these apparatus.

In closing, I have only further to observe that I am deeply conscious of the incomplete form in which the subject has been submitted, more especially in relation to the apparatus last described. My apology lies chiefly in the extent of the field to be overtaken. The labours of many inquirers would be required to determine the value of this mode of treatment in the numerous diseases to which it is applicable. I trust, however, that I may have succeeded, at least to some extent, in demonstrating its importance; and I hope, also, that I may have contributed means, however humble, to enable the profession to employ agents whose capacities both for good and evil are great, with that degree of precision which ought always to be aimed at in using remedies of every kind, and through which alone solid and lasting progress can be made in the science and art of medicine.

## CLINICAL MEMORANDA.

### CYANOSIS: MURMUR WITH THE FIRST SOUND OF THE HEART: PATENT FORAMEN OVALE.\*

A FEMALE child, five months old, was brought as an out-patient to the Children's Hospital on October 23rd. Its face and extremities were of dusky colour; it had cough, hurried breathing, and much palpitation, and a distinct murmur with the first sound over the heart. I did not ascertain whether this was propagated or not up the great vessels. The child had been dark-coloured from birth, and had had convulsions at intervals. It did not seem colder than others. The mother was not strong. She had suffered during pregnancy from palpitation and faintings, and at the seventh month had fallen down stairs. The child was born at the full time. She had two other children, healthy; and she had no cardiac disease. The child was ordered an expectorant and stimulant mixture, and I saw it once more and verified the presence of murmur. A few days afterwards it died in convulsions. On the following day I made a *post mortem* examination, at which Dr. Foster was present. The fontanelle was not closed. The abdomen was distended. The chest was markedly cone-shaped, the apex being at the neck. The surface was not so dark as during life. On opening the thorax, the lungs were in part pink-coloured and healthy; in part dark and collapsed. The pericardium contained more than the usual quantity of serum. The heart was larger than normal, but in its ordinary position. The right cavities were larger than the left, and contained clots; the left were empty. The walls of the right ventricle were somewhat hypertrophied. The aortic and pulmonic valves were healthy. We examined carefully the orifice of the pulmonary artery, and there was no contraction about it; on the contrary, it was, if anything, larger than usual: it was so far larger than the orifice of the aorta that it admitted my little finger readily to the second joint, whilst the aorta admitted the same only to the first joint.† The foramen ovale was pa-

\* Read before the Pathological and Clinical Section of the Birmingham and Midland Counties Branch.

† Dr. Foster has obliged me with the following measurements as to relative size of aortic and pulmonic orifices in females (from Bizio), from which it will be seen that the latter is normally the larger. The circumference is given in English inches:—aortic, 2.557; pulmonic, 2.674.

tent, admitting a goosesequill above the edge of its imperfect valve. The Eustachian valve was well developed. The liver was large.

The interest of this case lies specially in the fact of a murmur being heard without there existing any other condition to account for it than the open foramen. There was no contraction nor abnormality of the pulmonary artery; and thus the case supports the views of Dr. Markham, and those expressed by Dr. Foster in his paper on the subject in the *Dublin Quarterly Journal of Medical Science* for August, 1863.

EDWARD MACKEY, M.B.Lond., Extra Acting Physician to the Children's Hospital, Birmingham.

#### MECHANICAL DYSMENORRHOEA AND CHRONIC ENDOMETRITIS.\*

IN the following case, mechanical dysmenorrhœa and chronic endometritis were cured by dilatation with laminaria-tents and the application of a solution of nitrate of silver to the uterine cavity, the result being remarkable fecundity. The patient was thirty-four years of age, well formed, and healthy-looking. Her case was characterised by a history of long continued menstrual trouble, dating from the first catamenial epoch—pain in the left hypochondrium, symptoms of spinal irritation, hysteria, and dyspepsia. The menstrual flow usually lasted seven or eight days, but brought no relief to the pain. Marriage in 1867 brought no change: on the contrary, an attack of menorrhagia aggravated her condition. The lips of the os being found excoriated, and the cervix congested, blood was taken by puncture, and nitrate of silver applied, but without much benefit. Finding considerable contraction in the cervical canal and os internum, I dilated it with laminaria-tents, of which two were used, at an interval of ten days; and a solution of nitrate of silver (two scruples in an ounce) was applied twice a week to the interior of the uterus. Marked benefit ensued. The next three catamenial periods passed off without any suffering. Pregnancy then occurred, and she was delivered of a full-grown female child at term; which, however, she could not suckle. After passing two more periods naturally, pregnancy again occurred. She went the full time, and was delivered of another healthy infant. This she was also unable to suckle. For the third time pregnancy ensued at the end of three months from her last labour. She went the full time as before, and on this occasion gave birth to three female children, all well formed and healthy. She was unable to suckle them. Two died within the month, and the third is now in a state of slow decline. Thus this poor woman gave birth to five full-grown infants in the short period of one year and ten months.

ALFRED HALL, M.D., Brighton.

#### OBSTETRIC MEMORANDA.

##### RUPTURE OF MEMBRANES SEVEN WEEKS BEFORE DELIVERY.

A CASE similar to that mentioned by Mr. Bradley occurred to myself. On June 30th, 1866 (whilst acting as assistant to Mr. Woody of Tamworth), I delivered a woman, aged 30, of her fourth child. The membranes had ruptured seven weeks previously, and the liquor amnii had been dribbling away ever since. As with Mr. Bradley's case, symptoms of labour occurred with the first discharge of liquor amnii.

EDWARD NORTON, L.R.C.P.Lond., Maida Vale.

##### OBSTRUCTED LABOUR.

THE case related by Mr. Johnson in the *JOURNAL* of November 25th recalls to my mind one, though quite dissimilar, which occurred in my practice some five years ago.

Mrs. C., aged 38, was taken ill in labour for the first time on January 29th, 1866. She had been married twelve years. An unqualified man attended her as my assistant, and came for me, saying it was a case for Cæsarean section. On examination, I could only pass my finger about two inches within the vagina. There I found a hard unyielding structure, feeling like cartilage, in which was a small hole, only admitting the tip of the finger; so that I was unable to ascertain the state of the os. The pains, which were strong and regular, caused no pressure upon it. After waiting for some time, I made four incisions with a hernia-knife into the circumference of the aperture, in opposite directions; and then, finding the os freely dilated, I ruptured

the membranes. The labour was terminated in the natural way in about two hours. The patient had a good recovery, and, I have been told, has borne two children since without surgical aid.

Walsall.

JAMES CLARK, M.D., F.R.C.S.E.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CASE OF HEART-DISEASE WITH LOUD MUSICAL MURMUR, WHICH PASSED AWAY.

(Under the care of Dr. DUCKWORTH.)

W. D., aged 28, porter, a rather spare pale-faced man, with brown hair, weighing 9 stones 3 pounds, came to the out-patient room complaining that he had suffered from night-sweats for about a fortnight; also that a noise was audible in his chest both to himself and to his wife at night when in bed. The latter complaint had existed for three or four months previously. He had never had any important illness, certainly not rheumatic fever; and he declared that he had led a temperate and regular life. For four or five years past he had been somewhat short-winded. Eleven years before, he had sustained a severe blow on the left side of the chest, but not over the præcordia. His father died of phthisis; also a brother. His mother and one sister were living and healthy.

The finger-ends were somewhat dusky. His pulses were generally visible, and of aortic type. The cardiac impulse was very extensive and wavy. The apex-beat was in line with the left nipple in the fifth interspace. There was a thrill of diastolic rhythm on palpation. The first sound was clear; but a loud purring and musical murmur replaced the second sound all over the chest. The murmur was of maximum intensity at the right base of the heart, and was loudly conveyed to the ensiform cartilage. It was, moreover, clearly audible along the aorta, down the back, and even on the parietal regions of the cranium. There was no anæmia. An emplastrum opii was ordered to the præcordia; and five grains of citrate of quinine and iron were given thrice a day out of infusion of calumba.

The patient did not return for a fortnight, when it was found that the loud murmur had entirely ceased; and a double bellows-murmur was heard at the base of the heart, and generally over the cardiac region, not being audible behind. The impulse was as before; and the pulse had the same characters, about 120. The man was well aware that the noise had passed away from his chest. The night-sweats continued. Careful examination of the lungs revealed no morbid signs; and the chest expanded well. Some streaks of blood were seen in the sputa during a bad cold two years ago. Three grains of oxide of zinc, with two grains of extract of hop, were ordered at bedtime each night; and the draught to be continued.

In a week, the man reported that he felt much relieved, and he hardly suffered from the night-sweats. In ten days, this latter symptom had returned as severely as before. There was no change in the physical signs in the chest. Pulse 128, visible, of aortic regurgitant type. A draught with some dilute acetic acid was ordered at nights, to replace the zinc pills. The patient ceased to attend from this date.

COMMENTARY.—It was to be regretted that this patient passed from further observation. Cases of transient musical cardiac murmur, though not perhaps common, are well worthy of study. In this instance there could be no doubt that there was progressive disease at the aortic orifice, and it is most likely that the loud and musical noise was due to a phase in the growth or development either of true vegetations about the sigmoid valves, or of a fragment of fibrinous deposition in connexion with the same. It is perhaps not too much to aver that the loudest and most distinctly musical cardiac murmurs are generally due to the presence of fibrinous masses about certain valves: moreover, musical murmurs are conveyed further along the arteries than any other kind. The fact of their fleeting character lends much support to this view of their origin. It is of course in such cases that there is risk of various visceral infarctions, more especially of the spleen and kidneys, and also of the cerebral arteries. There was, however, no reason to believe that such events had occurred in the above case. It is exceedingly common to find no antecedent rheumatic history in like instances, and the causes of the endocardial degeneration must be sought in other directions. Such changes often proceed slowly, and lead sud-

\* Read before the East Sussex District of the South-Eastern Branch.

denly to rupture of valves or tendinous chords, whereupon murmurs are generated, and such may change their character from day to day, varying, no doubt, with the form, amount, and texture of the new growth or the fibrinous deposition thereon from the blood-current.

It is proper to consider whether the severe injury to the left side of the chest eleven years before had anything to do with the cardiac lesion. In such a case pleuro-pericarditic adhesions might have occurred to an extent sufficient to damage the due nutrition of the heart, but there was no evidence of this, and it is probably quite fair to leave this part of the history out of consideration.

From this patient's family history and his severe night sweats it seemed likely that he might be phthisical, but as stated above, there was no evidence of such disease in the chest. The urine was not examined, or, if it was, no note was made as to its condition. In such a case it is of much importance to know whether or not the kidneys are sound, for aortic disease is not uncommonly associated with renal degenerative change.

It is noteworthy how much relief to the night sweats followed the use of oxide of zinc, although the remedy soon lost its power over this symptom. The opium or belladonna plaster, and the use of steel and quinine in these cases, are often of marked service, while digitalis is as certainly contraindicated.

### ST. THOMAS'S HOSPITAL.

FRACTURE OF THE LOWER PART OF THE SPINE FROM A HEAVY LOAD.

(Under the care of Mr. LE GROS CLARK.)

AN interesting case is now under treatment in this hospital of fracture of the lower part of the spinal column, from carrying an over heavy burden. The man was carrying a weight upon his shoulders, when it crushed him down forward, and fractured the spine. Mr. Clark stated that he had seen many such cases when the railway system was not so developed as now, and when the tunnels were being made. The men sat doubled up with their chins almost on their knees; and it was not uncommon for a mass of earth to fall upon them in this position, so heavy that the spine was forced to yield. As might be expected in these cases, the fracture commonly occurred towards the lower part, where there is an increase in the length of the leverage, and where the spine is not supported by the ribs and their attachments—that is, in the lower dorsal or lumbar region. The interest of the case in St. Thomas's is, that the nerves which supply the limbs seem to retain their function.

OPERATIONS, WEDNESDAY, DECEMBER 6TH, 1871.

*Sequestra in both Femurs.*—Mr. Sydney Jones had a case requiring the abstraction of sequestra from both femurs; but in consequence of the low condition of the patient, and his having serious heart-disease and great albuminuria, he only operated on one leg. After some chiselling of the outer side of the right femur, he was able to remove a very curious sequestrum an inch and a half long, and a number of smaller pieces. The use of the trephine was useful in two places. As he could not discover any trace of dead bone near the original cloaca, he concluded that he had taken away all the source of mischief in that bone.

*Excision of Knee-joint.*—Mr. Jones also excised the knee-joint of a girl aged 7, where the disease had lasted for two years. The girl had been under his treatment in the old Hospital. The pain in the knee and about it was most excruciating when the part was touched, and the leg was perfectly useless in consequence of the joint being bent and fixed. On an incision being made, the articular surfaces and the bone below were found extensively diseased; these were removed, and it is hoped that she will now enjoy a very useful limb.

*Disease of the Ankle-joint.*—Mr. Croft operated on a young man for disease of the tarsus. He had been operated on a month before for extensive disease of the os calcis and ankle-joint. In the former operation, Mr. Croft had left the joint between the astragalus and scaphoid open, as well as the articular surface of the cuboid. He gouged out the disease of the os calcis, as he supposed. Since then the joint had closed up, and only granulations could be felt on the surface of the cuboid. The remaining portion of the os calcis was now in a state of complete disintegration, and the present object was to remove the carious bone. After this was done, the cavity was filled up to keep it dilated, and, if possible, to encourage the necessary development of bone to preserve the walking power of the foot. This man had consulted some of the

surgeons of Paris on his case; but they could only propose amputation as a remedy. Mr. Croft hoped that this would be unnecessary.

*Case of Strangulated Hernia.*—The patient was a woman, who had suffered for some time with double inguinal hernia. On the morning of November 29th, the hernia on the left side came down before breakfast, and became irreducible; and pain began in the epigastrium. Shortly after breakfast she was sick, and in the course of the subsequent week had had pain on several occasions after taking food. The bowels had not been open since November 30th. The hernia of the right side remained quite reducible. The difficulty of the case lay in the extreme fatness of the patient. However, behind a thick mass of fat, the hernial tumour could be distinctly felt. Her temperature was high, the pulse quick, and symptoms of fever had appeared, calling for an early operation. Mr. Croft cut down upon the sac, which he carefully dissected, and, by a puncture, let out a small quantity of fluid like port wine and water. In the sac, he found the small, dense, and smooth piece of intestine. The stricture was found distinctly at the internal ring, and divided. The intestine, when returned, was of a very deep colour, and had a most disagreeable smell. However, as there were no adhesions, and the surface was perfectly smooth, Mr. Croft thought she might make a very good recovery.

### MIDDLESEX HOSPITAL.

PLACENTA RETAINED FOR THREE MONTHS AFTER AN ABORTION, CAUSING HÆMORRHAGE.

(Under the care of Dr. HALL DAVIS.)

MR. J. W. LANGMORE, M.B., Resident Obstetric Assistant, has kindly supplied the following particulars.

A married woman, aged 28, applied at the Middlesex Hospital, stating that she had been suffering for three months from abundant uterine hæmorrhage, accompanied by sharp bearing-down pain. The symptoms dated from a miscarriage in the fourth month. The patient was weak and anæmic; the uterus still a good deal enlarged; the os was nearly closed, and rather soft and congested. She was ordered twenty-minim doses of liquid extract of ergot in acid infusion of roses three times a day. She returned three days afterwards, saying that the pains were more severe, and the hæmorrhage still abundant. She was passing clots. She was ordered to continue the mixture. At the end of the week she came again, and brought a small mass, about three inches by one, which she had passed on the previous day from the vagina. It proved to be the placenta, with the stump of the umbilical cord attached. It was quite fresh and free from smell. The flooding at once ceased, and the patient recovered rapidly. She had called in a medical man after the miscarriage; but the ovum had been thrown away before he came.

### CHARING CROSS HOSPITAL.

LARGE CONGENITAL NÆVUS OF FACE: OPERATION: RECOVERY.

(Under the care of Mr. BELLAMY.)

A. B., aged 6 months, was brought as an out-patient to the hospital in May last, with a large congenital nævus, occupying the greater part of the left cheek, about one half of the upper lip, a portion of the ala and side of the nose, and the inner half of the upper and lower eyelids of the same side. The nævoid tissue implicated the true skin very deeply. Chloroform having been administered, Mr. Bellamy transfixed the greater part of the implicated tissue with two harelip pins diagonally, and tied the mass with a stout ligature. From some want of attention the proceeding was unsuccessful; and on the next visit Mr. Bellamy passed a stout needle under both the facial artery and vein as they passed over the jaw, a second under the left coronary vessels, and a third enclosing the angular vessels at the root of the nose, retaining them by twisted sutures.

The mother brought the child to the hospital in a week's time, with the contents of the constricted nævus converted into an abscess, pointing at the conjunctival surface of the lower eyelid. A scalpel was passed between the superior maxilla and the skin, and a great quantity of pus evacuated. The needles were withdrawn, and the cheek was dressed with wet lint. All went on well; and when the child was last seen, on October 11th, there was scarcely any evidence of the former disfigurement, excepting one or two small circoid points at the extreme outer margin of what had been implicated tissue. There was no contraction of the cheek or eyelids, from which appendages the nævoid tissue had almost disappeared; and there was every appearance of complete recovery.

## GENERAL HOSPITAL, NOTTINGHAM.

## CASES OF HYDROPHOBIA: WITH REMARKS.\*

By GEORGE ELDER, M.B., Junior House-Surgeon to the Hospital.

[Concluded from page 643 of last number.]

CASE IV.—On the evening of January 7th, 1871, the fourth and last case which I shall mention was admitted into hospital under the care of Mr. Wright. Ten weeks previously, the patient had been bitten by a dog at Calais on the left forefinger. Lunar caustic was at once applied to the wound by a medical man. The patient, whose health had been bad for a twelvemonth before the infliction of the bite, felt much as usual, until the night before admission. Just before going to bed, he attempted to drink a quantity of rice-water, when spasmodic action of the muscles of respiration ensued. During the night that followed, sleep was entirely prevented by their frequent recurrence.

On admission, the patient was noticed to be a sallow yet fairly nourished man of 30 years. The expression of the face was haggard, anxious, and frightened in the extreme. At and around the cicatrix of the bite there was an erythematous blush, but it was not the seat of pain. To the hand, the body felt hot and moist. At the wrist, the pulse was soft and uncountable. Frequently spasms occurred, during the duration of which the breathing was very laboured. The patient could only breathe in the sitting posture. In this case, whilst cold air, or attempts to eat and drink induced spasms, the same effects were produced by the mere mention of water. Great thirst and pain in the throat were complained of. His mental faculties were unclouded. His volubility in describing his symptoms, coupled with the cheerfulness which pervaded his remarks, was remarkable. He kept constantly spitting viscid saliva tinged with blood. From 9 P.M. till midnight he received three draughts of chloral hydrate, amounting in all to eighty grains, with the effect of decidedly diminishing the frequency and severity of the spasms, and rendering his condition more comfortable. About 10 o'clock on the morning of the 5th the saliva became tinged with blood; and the patient complained of distressing cardiac palpitation and pain, coupled with extreme weakness. At no time was his manner excited or irritable; on the contrary, he was remarkably quiet, hopeful, and occasionally jocular. Frequently during the day he sucked ice, expressing himself thereby much refreshed. Occasionally he was delicious; but more often his answers to questions resembled those of a man semi-intoxicated. During the last hours of his life large quantities of "coffee-ground" matter were vomited. At 6 P.M., after a sleep of two-and-a-quarter hours' duration, the skin was felt to be clammy and cold, and the pulse soft, quick, and irregular; respiration was slow and stertorous, and now the patient assumed the recumbent posture. Spasmodic muscular actions were of short duration, but not severe, and succeeded each other rapidly. He lay with his eyes shut, but not asleep, or unconscious, for at this moment he recognised his mother and brother, but could not return answers to their questions: so weak was he, that he was unable to spit out the bloody saliva which kept trickling from his lips. Gradually becoming weaker and weaker, he died of exhaustion at 10.30 P.M.

During the last day of his life, 440 grains of chloral hydrate were administered to him, with the happy effect of at least robbing the disease of most of its terrors.

The *post mortem* appearances were similar to those seen in the other cases, with the addition of aortic constrictive disease and hypertrophy of left ventricle.

REMARKS.—In all recorded instances of hydrophobia, a period of incubation, varying from a few days to some years, but generally, as in our own cases, varying from eight to nine weeks, intervenes between the infliction of the bite and the commencement of the disease. At the termination of this season a feeling of *malaise*, which usually takes the form of a cold, is felt by the patient. This constitutes the premonitory or first stage of writers, and may last from a few hours to two days, as in our first case. An inflamed condition of the cicatrices is by no means a regular concomitant of this stage. In only one out of the four cases was any abnormality visible; that simply being a slight erythematous blush, unaccompanied by pain. At the termination of the premonitory stage, the disease assumes its distinctive character. In all our cases the dread of water was particularly well marked. The respiration at this juncture assumes a peculiar sighing character, occasionally varied by difficulty of breathing and gasping, due principally to spasm of the muscles of respiration. The spasms seem to be due to the extreme hyperæsthesia of the afferent nerves of respiration. If examined, the pulse will be found to be rather quicker and

fuller than normal, and the skin hot and dry. There are also generally extreme thirst and dryness of the mouth and throat, with occasional pain referred to these parts. The expectoration of mucus, at first clear and frothy, then viscid, and latterly tinged with blood, seems to be an almost constant symptom. In none of our cases did I once meet with the "barking" noise often alluded to in essays upon the subject. The knowledge that eating and drinking aggravate the disease, instinctively as it were, seems to curb the desire for solids and liquids; but the bodily sufferings, however terrible, are not the worst which the patients have to bear. Usually in disease night brings some respite to the sufferer but in hydrophobia, night and day, mind and body are both on the rack. At the outset of the second stage, the patient is usually quiet; but, as its end draws near, delirium, or occasionally, as in our first case, maniacal fury, supervenes. After a shorter or longer period, according to the age and previous health of the patient, the third or exhaustive stage begins. Now all the symptoms appear in miniature. The spasms, which before had been so terrible in their intensity, without losing in frequency, perhaps diminish in power; the respiration becomes feeble—very feeble—yet retains its peculiar sighing or gasping character, or at times is stertorous. From being dry and hot, the body feels clammy and cold, or, it may be, becomes livid towards the last; from being well nourished, it becomes shrivelled and emaciated; and the face, sharing in the general decay, becomes prematurely old, whilst from the lips slowly trickles the blood-stained saliva. In three out of our four cases, consciousness remained almost until death. Generally death from exhaustion ensues on the third or fourth day. The average duration of our cases was three and a half days. The symptoms during life seem to point to some part of the cerebro-spinal system as the seat of the diseased action—probably the medulla oblongata—yet, so far, pathology has not confirmed this. Neither has chemistry been more successful; so that we are obliged to construct a theory of hydrophobia based upon its analogy to other diseases. No one, I think, will dispute that this malady is due to a poison transmitted to man by the saliva of the rabid animal. This being admitted, the disease is brought within the pale of those due to blood-poisoning. The treatment of hydrophobia resolves itself into the prophylactic and the remedial. With regard to the former, lunar caustic does not seem to give security against the invasion of the disease. Whether stronger escharotics may be more trustworthy, I cannot say; but certainly, when the operation can be performed without seriously affecting the after usefulness of our patients, excision of the bite or bites should be at once performed. When the disease has declared itself, besides careful hygienic and dietetic observances, it will demand all our tact and discrimination in the use of remedies. In our four cases, chloral hydrate alone possessed any influence over the disease; it acted simply by deadening the nervous sensibility, thus destroying in great measure the power of reflecting impressions possessed by all nerve-centres. If the disease be due to blood-poison, is it not possible that we may convert what has hitherto been an incurable affection into a curable one, by the administration of drugs calculated to destroy the poison or eliminate it from the system? Although at the present time our knowledge of septic agents and antiseptic remedies is limited, still, with the first-mentioned object in view, a preparation of carbolic acid would seem to offer the best chance of success. From its ready solubility and consequent speedy access to the blood, the sulphocarbonate of calcium should be preferred. The remedy should be given in large and frequent doses. Baths, either moist or dry, which have not, so far as my reading goes, been tried in any well authenticated case in this country, would offer the speediest method of effecting elimination.

Since the preparation of this paper, another case has occurred in this hospital, an account of which I am, through the kindness of Dr. Robertson and Mr. White, enabled to give.

CASE V.—The patient was admitted on May 30th, 1871. Ten weeks before admission, whilst playing with his own dog, he was bitten on the under surface of the left thumb. For some days previously, the dog had been shy and evidently "out of sorts." Immediately on the infliction of the bite, nitrate of silver was freely applied to the wound. Rather more than two days before admission, the patient felt as if suffering from a severe cold; but, coupled with what he thought to be the decidedly "catarrhal symptoms," there was a difficulty in swallowing. On admission, the patient, a very muscular and well-proportioned man, looked frightened and haggard. The eyes were staring, and the face was pallid. The whole body sweated profusely. On attempting to drink, the muscles, especially of respiration, were thrown into violent spasm. There was no disturbance of the mental powers. The cicatrix of the bite was not the seat of pain or of inflammation.

On the day of admission, at 4.30 P.M., and again at 6.15 P.M., two forty-grain doses of chloral hydrate were administered *per rectum*. So much was his condition improved, that between the latter mentioned

\* Extracts from a paper read at the Midland Branch of the British Medical Association.

period and 11 P.M., he several times slept, and ate an egg without seeming to suffer much uneasiness. Without difficulty, at eleven o'clock, a draught containing in solution thirty grains of chloral hydrate was drunk by the patient. During the night, he slept fairly, with occasional intermissions. In the intervals of sleep, two eggs were eaten, and a good quantity of ice was sucked, from which he derived much relief. Between 2 A.M. and twelve o'clock midnight on the 31st, nine thirty-grain doses of chloral hydrate were given; the first three *per rectum*; the remainder by the mouth. At 3.15 P.M. he ate and drank easily. Early on the morning of June 1st, whilst at his breakfast of bread and butter and tea, swallowing was observed to be rather difficult. He was also slightly delirious and excited. Towards noon, the difficulty of swallowing had disappeared. For dinner he ate a mutton-chop, and drank with apparent comfort half a pint of beer. At 7.30 P.M., he was quiet and dozing. Between 4 A.M. and 11 P.M., seven thirty-grain doses of chloral hydrate were taken in milk. The case underwent but little change during June the 2nd. At 2 A.M., he was very restless, and swallowed with difficulty. As the morning wore on, the difficulty increased; the tongue swelled; the eyes became congested; and the patient talked or sang incessantly. Yet abundance of nourishment, both liquid and solid, was partaken of during the day, and now and then he slept. In six portions, from 2 A.M. until 10.15 P.M., 240 grains of chloral hydrate were swallowed by the patient either in milk, beef-tea, or iced water. On June 3rd, slight spasms were noticed for the first time since the patient had been under the influence of the drug. For dinner he ate a chop and drank half a pint of beer; during the day he had also several eggs and two or three pints of beef-tea. From 1 A.M. until 11.30 P.M., 330 grains of chloral hydrate were given in seven doses. On the following day, the swallowing became very difficult, yet not so much so as to prevent the injection of solids and liquids. Occasionally, he had a spasm more decided and more severe than those noted as occurring on June 3rd. He was restless, evidently much exhausted, and slept but little. Only 90 grains of chloral hydrate were taken on June 4th. At 2 P.M. on June 5th, he died. Up till within an hour of his death, he was able to swallow solids and liquors with comparative ease.

A *post mortem* examination, made a few hours after death, revealed nothing more than was observed in the other cases.

**REMARKS.**—This case is chiefly remarkable for its duration, and the marvellous way in which the spasms were kept in check by the administration of chloral hydrate. No doubt the long duration of the case was in great measure due to the ease with which large quantities of solids and liquors were taken. Neither was there in this case any of those severe paroxysms of muscular spasms which soon wore out the first case. From the admission of the patient into hospital until the time of his death, none of the most horrible features of this frightful malady were observed.

## ROYAL UNITED HOSPITAL, BATH.

### MALIGNANT DISEASE OF CÆCUM.

(Under the care of Dr. COLE.)

For the following interesting report we are indebted to Mr. L. W. Marshall, M.B.

J. D., housewife, was admitted on July 24th, 1871. There was no history of any hereditary tendency in her family. She had for the past two years suffered from failing health, but, until three months since, has been able to attend to the duties of her house. At this time she was seized with violent pain in the right hypochondrium, which continued, to a more or less extent, up to the time of admission, being accompanied by great depression. On admission, she was pale, emaciated, and of a sallow complexion; she complained of great thirst, nausea after taking food, anorexia, and depression. The tongue was pale and flabby, but clean; the bowels were constipated. On pressure in the right hypochondriac and lumbar regions, signs of great pain were elicited; at the same time some amount of resistance was felt, giving the impression of a hard firm mass being present immediately beneath the surface. The ascending colon was distended with flatus, and the abdomen was swollen generally, but a bulging was perceptible on the right side. She complained of slight dyspnoea, which, however, was unattended by cough, the respiratory sounds being somewhat loud and coarse. No increase of hepatic dulness was discoverable. The cardiac sounds were normal. The catamenia were regular, but scanty. The urine was scanty; it contained no albumen, was of specific gravity 1.019, and acid; pulse 100, small and feeble; temperature 100.2.

Until August 5th, she remained much in the same condition, both

pulse and temperature being high, whilst the bowels were relieved by enemata; but on this day she vomited, and the pain became much more severe, the prostration also being considerably increased. A vaginal examination was made on this day, when the uterus was found to be antverted. On August 6th, the pulse was 116, feeble; temperature 103. She had had a bad night; vomited twice. The pain was still severe; the bowels open; the abdomen was much swollen and tympanitic. On the 7th, the pulse was irregular and intermitting; the temperature 101.2. Vomiting still continued; sonorous and sibilant râles were heard all over the chest. There was slight expectoration of a frothy nature. On the 8th, she sank rapidly and died.

**Necropsy** twenty-five hours after death.—Rigor mortis was present. The body was much emaciated, and of a sallow hue. The lungs were somewhat congested at the base, but otherwise healthy. The heart was fatty, but there were no valvular lesions. On opening the abdomen, large quantities of curdy serum escaped, and signs of general peritonitis were well marked. The ascending colon and cæcum were both firmly adherent to the abdominal parietes, and the cæcum was removed with difficulty; in doing this, a large abscess was opened into immediately behind it. The small intestines were adherent in many parts. On laying open the cæcum, a large ulcerated mass of a dark grey colour was exposed; the boundaries by which it was attached to the parietes were hard and firm. Three inches of the mucous membrane were removed in each direction. The lumbar glands were much enlarged, and all presented the appearance of encephaloid. The head of the pancreas was considerably enlarged, and hard and firm. On making a section of the liver (which was not enlarged), numerous patches of an "apoplectic" nature were discovered, and in the right lobe also five or six cancerous deposits, varying in size, having hard, firm edges, but soft and cheesy in the centre. Both kidneys were deficient in cortical substance. The uterus was large, and an erosion of the os was present.

## THERAPEUTIC RECORD.

**NITRITE OF AMYL IN ANGINA.**—Dr. H. C. Wood, jun., of the Philadelphia Hospital, records, in the *American Journal of Medical Sciences* for October, a case of severe angina connected with chronic mitral disease, in which on repeated occasions the inhalation of five drops of nitrite of amyl gave immediate and marked relief, and finally prevented the recurrence of the attacks.

**TOXIC EFFECTS OF CHLORAL.**—Prof. N. R. Smith of Baltimore, states (*Boston Medical and Surgical Journal*, July 20th, 1871), that four cases of a peculiar affection of the fingers, resulting from the use of chloral, have come under his observation. This affection consists of erysipelatous inflammation of the integuments of the fingers, with desquamation of the cuticle and ulceration around the border of the nails. He further states that three deaths have come to his knowledge from toxæmia caused by chloroform. The details of these cases seem to us too indefinite to fully establish the conclusions of the eminent author of this communication.

**COMPOUND SYRUP OF ASSAFCETIDA.**—Mr. J. J. Rambo, of New York, calls attention (*American Journal of Pharmacy*, September, 1871) to a formula for this preparation, which, he says, he has been for a number of years in the habit of preparing, to obviate the great objection felt by most patients to the disagreeable smell and taste of assafoetida, and which has prevented to a great extent the more general use of this valuable drug. "The formula I find to answer the purpose effectually, at the same time its medicinal qualities are enhanced by composition with syrup of wild cherry, possessing the valuable therapeutic properties of both. R. Infusi pruni Virginianæ, Oj; Assafoetida, ʒj; Sacch. albi, ʒxxiv; Magnes. carb., ʒij. Rub the assafoetida and magnesia with the infusion gradually added, so as to make a uniform mixture and filter; to this, transferred to a bottle, add the sugar and agitate occasionally until it is dissolved. As a result, we have a handsome syrup which does not differ in appearance from the syrup of wild cherry. The property possessed by the volatile oils of bitter almonds, cherry laurel leaves, bark of wild cherry, etc., containing hydrocyanic acid, of removing the odour of assafoetida has long been known, and advantages taken of this property by M. Maheir, a French pharmacist, to remove the odour from mortars and bottles with which it came into contact; but I am unaware that the fact has ever been applied to its administration as a medicinal agent."

## BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 9TH, 1871.

## THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

THE progress of the illness of the Prince has during the week been depicted in bulletins which, to medical readers at least, have presented quite unmistakable indications; and, while respecting the divinity which doth hedge those nearest to the throne, by avoiding unnecessary details, they have afforded almost as accurate a clinical record as if the thermometric figures and the bedside observations had been published. Thanks to the accurate labours of English and German observers—Stewart, Jenner, Murchison, Budd, Wunderlich, Niemeyer—we have a knowledge of the natural history of typhoid more complete than that of most other disorders. It has been aptly said that, to fulfil all its purposes, a medical bulletin should so ascend from details of fact to generality of expression, that the verbal generalisation should enable the skilled reader to travel back from the generalisation to the particulars which it expresses, and reconstruct the case from the information which the bulletin affords. This has been so with the medical bulletins from Sandringham. Reading them from day to day, we have been able to follow the progress of the patient. On the one occasion, at the close of the week, when the evening temperature was beyond the normal excess of evening over morning heat in enteric fever, the bulletin distinctly warned us of the fact, of which we could all interpret the somewhat threatening indication. But we were able also to note its rapid subsidence; and, as there were still no complications, we were able to dissipate the fears of immediately impending peril which the case of Lord Chesterfield had vividly impressed upon the public mind. We know well what is the “fever-process” in typhoid, and what is meant by its being severe but regular. It is not the part of the bulletins to prophesy; nor can this function be safely assumed even by unofficial critics of them. We can therefore only say now, what all educated physicians have by this time been able to say to those who have questioned them: that, in such a case as this, the process of the fever is not likely to be completed before the twenty-eight or perhaps even the thirtieth day; and that, meantime, positive predictions are out of place, for the events of typhoid sometimes occur at a moment when least expected. But we may also say that any but a favourable termination would now be contrary to the probabilities; while of course, when we last wrote, it was still in the region of doubtful and almost open questions. We may say, too, that the bulletins are not less cautious than they are accurate; they encourage no false hopes, and conceal no sinister events. They are altogether to be trusted; and the very favourable anticipations which on this twenty-fourth day arise from them are legitimate and well-grounded.

We turn now to a question—which we see with pleasure is occupying a large share of public attention—that of the causation of the illness. If impressive lessons such as those which are to be derived from the recent sufferings from typhoid disease of our own royal family, and of the reigning family of Portugal, are to have their just and appointed influence, it can only be by strictly investigating and rightly applying their teachings.

The origin of the sufferings of a high personage, to whom a nation is deeply attached, will always have something more than a private interest. When his illness is one of a preventable character, and due to causes which we all recognise as ignominious and preventable incidents, but which annually strike with death many thousands of our population, the conclusions to be derived from the study of the origin of the illness have a national importance, and the duty of investigation assumes a serious character.

We stated last week, in detail, a number of circumstances which led to the belief that the local origin of the fever of the Prince was sewer-poison imbibed in air or water while at Scarborough; and, added to the fact that a groom, who had not been at Scarborough, was subsequently taken with enteric fever while staying at Sandringham, this pointed to the necessity of a twofold investigation. This we have assisted to institute, from information kindly volunteered from various sources, and by direct inquiry.

In entertaining a royal guest, a gentleman does not the less remain the master of his own house. We communicated, therefore, in the first instance, with Lord Londesborough, and placed at his disposal the services of a metropolitan hospital physician, whom, with his permission, we requested to proceed to Scarborough for the purpose. Lord Londesborough very readily facilitated his inquiries, and Mr. G. P. Dale, F.R.C.S., and Mr. Peacock, kindly afforded assistance by his direction.

The report which we publish gives details which we may briefly sum up, by saying that it shows conclusively that the construction of the Lodge affords in perfection all the conditions fitted to favour the introduction and propagation of the enteric poison. We abstain altogether from the discussion of the recent question whether the fermentation of sewage and its evolved emanations induce typhoid by the production anew of the poison, or by the multiplication and propagation of a pre-existing germ-poison already present in the sewage-matter or gas. It is a point which is here not practical, although otherwise of high importance. The conditions were equally favourable to the introduction of the enteric virus under either circumstance. Here was a house, ill built and difficult to ventilate, with thirteen communications with cesspools. In the basement and inside the house are two cesspools, into which all refuse passes. Turning to the published certificate of the architects and contractors attached to Mr. Dale's letter, we find that they state that “we have carefully examined the drains and cesspools at the above Lodge, both inside and outside the building, having had them opened for the purpose”; and they describe them as perfect. It will be seen, however, that this statement was somewhat hasty. One of the gentlemen who signed this certificate accompanied our representative through this part of the inquiry, and admitted that the cesspool most likely to be the source of evil—if such be chargeable to the place—was not opened, and had not been opened, so far as any evidence could be obtained, for at least six years: in fact, there was not any available evidence to show what date it had been opened, if at all, since the reconstruction of the drainage. We say that this was the most important of these most obnoxious appendages to a house—cesspools—because this particular cesspool received the drainage of five out of six closets. It was in the basement immediately below the cabinet of the bedroom occupied by the Prince; and that cabinet which opened into the Prince's bed-chamber, and with which this cesspool was directly connected by a pipe about ten feet long, had no through-ven-

tilation. These cesspools—abominable and dangerous superfluities—emptied themselves into sewers which ran by a common outlet downward towards the sea, and joined the system of common sewers of the south district of Scarborough.

As to this sewer system, we may state that it is, at and above the point of junction, subject to great backward pressure from the influence of the tides. This and other circumstances mentioned in our detailed report, produced so great a pressure of sewage-gas upon the traps, in the absence of ventilation of the sewers, that the most efficient and complete traps—at the best very delusive contrivances—could not resist it. And during the reflux of the tide, this house, with its thirteen sewer-openings, and its cesspools beneath, would be subject to frequent inundations of the sewer-gas. We may add that we are informed from an independent source, that, when the present system of drainage was being constructed at Londesborough Lodge, "after the workmen had very thoroughly done their work, there was such back-draught up the drain that it blew the candle out, and would have blown out a dozen if they had been there." The contractor admitted that at certain times there was great pressure of gas on the traps, and that no traps could withstand it.

As to the epidemic conditions of the town specially relating to typhoid fever, we have been favoured by the Registrar-General with the opportunity of examining the registration records to this date, which show the following results.

In the quarter ending September, the following deaths from typhoid fever occurred in Scarborough: on the 12th July, a female, aged 42, in Nelson Street; July 31, a female, aged 40, in Brook Street; Aug. 19, a female, aged 4, in Brook Square; August 28, a male, aged 20, in Burmiston; Sept. 25, a female, aged 11, in Church Street; Sept. 27, a female, aged 5 years. There are also two deaths which he has registered as typhus, one as continued fever, and one with disease not named, but symptoms which are the usual complications of fatal typhoid. Since the commencement of the present quarter, there have been registered as dying from this disease a male, aged 5, at Hyde Park Terrace, 17th Nov.; a male, aged 5, at Cook's Row, 29th Nov.; a female, aged 5, 17th November—the last two being of the milder form known popularly as gastric fever; four cases from typhus, a case of "fever" and of "infantile remittent fever", also typhoid, in a child aged three.

Finally, we may say that typhoid fever has existed, and at this moment exists, in at least one district, Ramsdale Hill, whose sewers fall into a common outlet with those of Londesborough Lodge; so that the back-draught might have carried back to the Lodge any poisonous emanations with which the common sewer was charged.

As to the vital history of the case, we have already mentioned the fact that a large proportion of the party assembled to meet His Royal Highness became affected by diarrhoea, etc.; and we have now to add the highly important and authenticated statement that, besides the illness of His Royal Highness and Lord Chesterfield, two other persons—servants employed at the house at the time—are also suffering with typhoid fever. The one is a temporary servant of the Duke of Beaufort (who is not, as *the Grace* has well observed, a groom), and the other is a servant of Lord Londesborough. Moreover, it has to be noted that the visitor who occupied the Prince's room just before the Prince, was taken with diarrhoea; and we were informed that Lord Chesterfield occupied the same room after the Prince's departure, and this was the room of which the cabinet was immediately connected with the cesspool beneath.

There are other circumstances of which we have not lost sight. As to the general state of Scarborough, we may say that while the new town is fairly well sewered, the old town, which is the northern part, is one of the worst drained in England. It is, in the graphic words of one of our medical correspondents at Scarborough, "simply not drained at all—a mass of middens, and ash-holes, and bad stench. We want the Health of Towns Act—we have only a pseudo Local Board acting under the Council, which includes many strong economists." Moreover, the royal party were shooting for days from Ayton to Willoughby, "a low black swampy land, five miles of drains: Ayton, two years ago, was pregnant with typhoid fever; Old Scarborough has this summer never been free from low fever." They passed several times the disgusting public midden on the Seamer Road, which was very offensive, and was complained of at the time. The stench from this midden sometimes infects the air half a mile.

As Mr. Dale, whose candour and courtesy are much to be commended, has stated, the water used was that of the town and the "celebrated Bristol water". The town water we are having submitted to examination. The microscopical report is unfavourable. The chemical analysis is not yet complete. The "Bristol" water comes from the Hot Wells, Clifton, Bristol. It is, we are informed, "put into the bottles hot, and remains perfectly good for any number of years, without sediment." It is a beautifully clear and well-flavoured water, considered to be of great purity. We have been supplied with samples of it; and, as the test of most value in respect to the possible zymotic characters of such water is a physiological test, which cannot be completed within a week, we reserve any further comments upon it. We may say, however, that the physical conditions of the well are, we are informed on good authority, not beyond suspicion by the faculty in Bristol.

Thus far as to Scarborough. Further investigation has only tended to produce a twofold series of facts, from which the obvious deductions are well-nigh irresistible.

But it would not be satisfactory to omit an investigation at Sandringham. Here, however, we are in face of a different set of circumstances. General Knollys has very naturally and wisely, we venture to think, determined to undertake a satisfactory official investigation by proper persons, when His Royal Highness shall have sufficiently recovered to give authority and directions. Meanwhile, during the illness of the Prince, it would be obviously improper to make such structural investigations. In view of these circumstances, we should have thought it intrusive and improper to intervene with unauthorised investigations and curious perquisitions. There have, we believe, been many offers to undertake volunteer analyses of the water within the bounds of Sandringham, by which the house is supplied. These have been declined, inasmuch as it is intended to place the water in the hands of authorised persons. We shall content ourselves with stating, upon proper authority, that Sandringham House, which was only built two years since, is provided with a complete system of trapped and ventilated sewers; that it has an abundant water-supply from two wells within its limits, something like eight thousand gallons *per diem* passing through the drains; that this water was examined three years since by an eminent chemist, and pronounced good; and that the drinking-water cisterns are provided with filters. There is a separate well to the stable-yard; and Blegg, the groom who has been taken ill with typhoid, had been in London after coming from Scotland.

As to the health of the surrounding district, we may state that, in the whole of the widely extended superintending registrar's district of Freebridge Lynn, there was only one death registered from typhoid fever during the Michaelmas quarter, and that at South Wootton, six miles from Sandringham, in July. In the subdistrict of Hillington, which includes Sandringham, West Newton, and seven other villages, there have not been any deaths from typhoid since the commencement of the quarter. We mention West Newton, because it is not a healthy village, and lies close to Sandringham. Scarlet fever is prevalent there, and a low type of disorders generally. Its cesspools and wells require remodelling; and we trust that the attention which will probably now be called to it, will lead to much needed amendments. There have been four deaths registered from scarlet fever since September in the district. Last year typhoid fever was prevalent there, and was reported by Mr. Barrett of Grimston. But there has been none, as we are enabled to state upon his authority, since last year.

There is probably no district in this county of which the same could not be said of some of its villages. But the vague and distant suggestions thus engendered are of little force against the overwhelming facts that a large portion of the Scarborough party suffered the symptoms characteristic of mild and immediate action of the sewage-poison; that four adults of that party, going to different parts of the country, were, within the ordinary periods of incubation, seized with this identical fever, which comparatively rarely selects adults of this age; that the house itself has all the worst faults which seem specially, and even peculiarly, to breed and foster the poison, and offers all the conditions requisite for drawing in and diffusing the sewage virus from connected sewers. Add to this, the almost certainty that these sewers were at the time charged with the typhoid infection.

Should all these facts—one of the most striking series that can be mentioned—still fail to afford ground for reasonable conviction, they will, we trust, at least, have an effect still more important—that for which our labour has been expended, and towards which our efforts are constantly directed, of impressing upon the careless population and neglectful authorities of this country the necessity of paying attention to the construction of efficiently ventilated sewers, and the preservation of their drinking water from pollution. The present system by which every house-sewer is ventilated into our houses, and (by the waste-pipe) into our cisterns, costs us annually some thousands of valuable lives. We venture to hope that the lesson will not be lost on house-builders and engineers, who put their faith in delusive "traps", tolerate cesspools, and omit to ventilate the street and house drains.

#### VENTILATION OF SEWERS.

In the statements which have been made regarding the drainage and water-supply at Scarborough, with reference to the illness of His Royal Highness the Prince of Wales, little or no notice has been taken of the *ventilation* of the sewers. This, however, is a matter of great importance; for it has been shown that hurtful results are liable to arise where sewers and drains are trapped, on account of the extreme lightness of sewer-gas, if proper attention have not been paid to their frequent ventilation, especially at the highest outside points. In such cases, typhoid fever, when it occurs, as a rule does not attack the houses in the low-lying parts, but those in the higher localities. At Croydon, for instance, five or six years ago typhoid fever broke out, but affected only

the high and best parts of the town. The sewers and drains were found to be in good order and properly trapped; the water was pure; but there was no system of sewer-ventilation. Since then all the sewers and house-drains have been properly ventilated, and a case of typhoid has scarcely been known. Again, at the Orphan Asylum at Beddington, an outbreak of typhoid which occurred three or four years ago, was distinctly traced to the absence of outside ventilation for the house-drains, which discharged their gas into the various parts of the building. At Eastbourne, in 1868 and 1869, typhoid was prevalent, and in the high-lying parts of the town. Here there were ventilators, but they were blocked with charcoal, and, as the waste-pipes of the house-cisterns communicated directly with the sewers, they became, in fact, real sewer-ventilators inside the houses. A similar occurrence is mentioned by Dr. A. Carpenter as having taken place at the Warehousemen and Clerks' Schools at Caterham in 1867. In this latter case, the disease occurred in the colder period of the year, when ventilation by means of open windows was not much resorted to; and, the rooms being heated by hot-water pipes, there were no open chimneys to act as ventilators. Nearly forty per cent. of the children who used the classrooms in the morning suffered from typhoid fever. These schools are situated on the summit of a high country hill of chalk.

A system of sewerage cannot be held to be complete, or even proper, when the ventilation is not perfect. Traps are quite useless when the gas has reached a certain pressure, for it will force them; but with proper outside ventilation of the sewers, the communicating house-drains cannot ever store in them so much sewer-gas as will be sufficient to force a properly made trap. We must urge our medical brethren to impress upon those who have to do with these matters, that drain-traps will not give security and ensure freedom from poisoning with sewage-gas unless the sewers with which the drains communicate are thoroughly well-ventilated.

---

IN the case of *O'Reardon v. the Law Life Assurance Society*, tried in the Court of Queen's Bench on November 30th, a non-suit was entered, on the ground that the plaintiff had concealed from the Society material facts of ill-health at the time of assuring.

---

THE foundation-stone of the intended new building for the Tewkesbury Rural Infirmary was laid by John Surman, Esq., the President, on Thursday in last week, in the presence of a numerous assemblage, after special Divine service in the Abbey.

---

WE recommended some time since, that the extremely unprofessional pamphlets circulated by Mr. Washington Evans should be brought under the notice of the Council of the Royal College of Surgeons. We understand that this has been done, and that Mr. Evans's conduct is likely to form the subject of investigation at an early meeting of the Council.

---

A TELEGRAM from the Governor of Havannah announces that some medical students profaned the cemetery in which had been interred the remains of a Spanish journalist named Castanon, who was killed last year in a duel with an American, through a dispute in which Castanon supported the Spanish domination in Cuba. A Council of War had condemned several of the students to the galleys, and eight to death. The latter were immediately executed. This event had created a deep impression in Havannah.

---

THE French Government has conferred upon Dr. Vintras the Cross of the Legion of Honour, in recognition of the services he has rendered to his countrymen for the last ten years at the French Hospital and Dispensary in London. Dr. Vintras was in truth one of the most active founders of this hospital, and has never ceased to devote the utmost care to it. This physician was educated in this country, and the many friends whom he has made during his residence in London will welcome this well deserved recognition of his labours.

## THE LATE MR. DELAGARDE.

At the last monthly meeting of the Committee of the West of England Eye Infirmary, the following resolution was passed. "The Committee desire to record their sense of the great loss which the Eye Infirmary has sustained in the demise of its senior surgeon, Mr. P. C. Delagarde, F.R.C.S. His devotion to its interests continued to the latest moment of his life. His eminently skilful treatment of diseases of the eye, and his anxious solicitude for the welfare of the patients, to whom his kindness of manner greatly endeared him, combined, during the long period of thirty-five years, to render Mr. Delagarde a most valuable officer to this institution. His death is felt by the Committee to be an event that calls for an expression on their part of sincere regret at their loss, and at the same time of their cherished recollection of his eminent services to this Infirmary."

## SEWAGE-GASES AND TYPHOID FEVER.

AN outbreak of typhoid fever of the most serious but instructive character has broken out during the last few weeks, and is still in progress, in an institution in the south of London; and the occurrence is one of much interest, not only from the limitation of the locality of the fever, but from the fact that it aids to establish the connection between sewer-gases and typhoid fever. The following outline of the particulars has been communicated to us from an eminent and authentic source. The institution—a nunnery—contains about a hundred and fifty inmates, nuns and girls being educated. Some time ago, a grating was put across the main drain to prevent rats from coming into the house from the sewers. In consequence, an enormous accumulation of sewage took place on the side of the grating nearest to the house. When the drain was opened, sixty basketfuls were taken out. Ultimately, fluid sewage would not pass the obstruction; the drain burst; the basement of the house was flooded, and sewage percolated through the surrounding soil. The well which supplied the house with water was within a few yards of where the drain burst; but whether the water became contaminated or not, has not yet been determined. The first case of enteric fever occurred on November 1st, in a girl who had not left the convent for weeks; and since that time there have been thirty-seven cases and three deaths.

## SURGEON-MAJOR WYATT.

We referred recently to a letter addressed by Surgeon-Major Wyatt to the *Times* in connection with the late criminal trial at Dublin. We learn now that Mr. Wyatt was invited by the eminent surgeons who originated the intended manifesto to allow his name to be added to the list of signatures which appeared in the *Times*. Mr. Wyatt, who was then in North Wales, at once stated his willingness to testify to any expression of conviction that the utmost *bona fides* had been observed with regard to the treatment of the unfortunate wounded man, but that he regretted to be unable to sign the document, for reasons which were stated in reply; moreover, his original letter to the *Times* was forwarded to that journal through the eminent surgeon previously alluded to. These facts acquit Mr. Wyatt of that which has been laid to his charge, and will remove any unfavourable impression which such comments may have created. He responded loyally to the first invitation; and the extent to which he differed from the manifesto was laid before the surgeon who invited his attention to the subject, and received publication after passing through his hands.

## CERTIFICATES OF DEATH.

THE police reports inform us that a poor man residing in Clare Market made an application to Mr. Vaughan for advice under the following peculiar circumstances. He said his wife had been for eleven weeks an inmate of University College Hospital, and died that day week. The house-surgeon wanted to make a *post mortem* examination; but he (applicant) and his friends objected to this, and had the body removed to his home at once. The body was still unburied, as the surgeon refused to grant a certificate of death. Mr. Vaughan, after hearing the

application, ordered the house-surgeon to attend. The medical gentleman arrived soon afterwards, and said that he refused to grant the certificates until after a *post mortem* examination had been made, because he could not otherwise tell how the poor woman died. Mr. Vaughan, after addressing the surgeon severely, directed him at once to make out a certificate, or a summons would be issued. The dead body, it appeared, had been nearly a week in the poor man's room. It was in a coffin, and that was all that could be said of it; and it appeared that the body was to remain unburied because no certificate was granted by the surgeon. The surgeon said he did not think he was responsible, but bowed to the decision of Mr. Vaughan, and the certificate was subsequently granted. His worship observed that this appeared an important question. We quite agree with the able magistrate that this is an important question. It would be very satisfactory, therefore, if he would give to it a little more careful attention. It would be extremely satisfactory, for instance, if he would say how a surgeon is to give a certificate of death if he have not sufficient elements for determining what was the cause of death; and, unless a *post mortem* examination be made to satisfy the surgeon of what he cannot know without it, we should be glad to know how the surgeon is to obtain the information which the certificate requires. We should be curious to see the form of summons issued, and the degree of enlightenment which it would produce. We regret extremely that the surgeon did "bow" to the decision. It would have been much more satisfactory that he should have bowed to the magistrate and asked him to supply the elements for something better than a guess. There is quite enough, and more than enough, danger to the community already from the hasty and perfunctory manner in which certificates are often given now; and Mr. Vaughan, we feel sure, would be sorry to settle an important question in such a manner as to increase the existing sources of error in vital statistics and the facilities for crime. That will, however, we fear, be the effect of his remark, as reported; and would certainly result if surgeons generally were to suppose, upon his dictum, that they were to fill up a statement of the cause of death by guesswork. We hope the surgeon filled up that column with the single word "unknown". We hope Mr. Vaughan will remember that surgeons are officers only a degree less useful, and not less important in their sphere, than coroners. The surgeon should have called, in the extreme case, for an inquest, or let the body be buried on a coroner's warrant without inquest, if that functionary proved as easy-going as the Bow Street magistrate.

## INCREASE OF LUNATICS.

AT the last meeting of the Middlesex magistrates, Mr. W. H. Wyatt moved, pursuant to notice—"That the Court recognises the necessity of making further provision for the care of pauper lunatics belonging to the county; but taking into consideration that the county of Middlesex has already asylums at Hanwell and Colney Hatch, it resolves that the additional accommodation to be provided shall be of a character suitable for patients who may be determined to be incurable, but not dangerous to themselves or others, and who shall be draughted from the existing county asylums when it may become necessary, or expedient to make room for cases of a different class." He urged in support of this motion that they were bound to provide accommodation for the number of patients requiring admission. The motion was agreed to.

## ASSOCIATES OF ST. LUKE.

ON Monday evening last, the first ordinary meeting was held of a new religious society for medical students, called the "Order of Associates of St. Luke." A paper was read by the Secretary of the Society, upon the question of the lawfulness of the destruction of the foetus *in utero*; and, both in the paper and in the animated discussion which followed it, the moral and religious aspects of the question were specially considered. Professor Bentley occupied the chair, and students from most of the London hospitals were present. The society is established upon a distinctly Church of England basis; and, besides students and lecturers of the medical schools, a few clergymen share in the work,

attending the meetings, and taking part in the discussions, which are intended to be as far as possible limited to such religious subjects as specially concern medical students and practitioners. Such a course is likely to lead to some definite and practical results in the raising of the moral tone of medical students generally, and will commend itself to many students desirous of such mutual help, but unable hitherto to obtain it.

#### THE QUEEN'S HOSPITAL, BIRMINGHAM.

THE foundation-stone of the new wing of this hospital, the funds for which have been raised by the subscriptions of working men in Birmingham, was laid on Monday last, in masonic style, by Lord Leigh, Lord Lieutenant of the county of Warwick. After the ceremony, a luncheon took place at the Great Western Hotel, which was attended by above three hundred ladies and gentlemen, Lord Leigh presiding. Mr. Gamgee, to whom is eminently due the success which has so far attended the project of raising the working men's fund, in replying to the toast of "The Queen's Hospital", gave a history of the proceedings, and briefly described the plan of the new building. The cost he estimated at £20,000; towards which were already received, working men's contributions, £3,600; fund in aid, £2,450; together with interest amounting to about £240.

#### WARNING TO MOTHERS AND NURSES.

LITTLE children are sometimes dragged about by careless nurses in a most inconsiderate manner—especially where there is temper on both sides. A little girl about two years old was brought to the Great Northern Hospital to have an abscess opened in front of the axilla. When this was done, a large quantity of pus escaped. The mother stated that a fortnight before she had been hastily seized by one arm and lifted up by the girl who had charge of her. She was taken to a surgeon—Mr. Soutter—who declared that the pectoralis major had been ruptured. There was a clear and distinct groove between the two ends of the muscle, both being curled up like balls. Apparently the most perfect retraction of the fibres had occurred. Mr. Soutter bound the arm across the chest, to bring as far as possible the ends near each other. The child was kept quiet, and had nourishing food, etc.; but in spite of every measure suppuration took place; a large abscess formed, and for this the mother brought the child to the hospital. It is now doing well.

#### SANITARY STATE OF BAHIA.

IN consequence of the reported prevalence of malignant fever and of some other diseases, especially beriberi, in Bahia, the inspector of health, Dr. Siqueira, has made an official report on the health of the city. He says that at the date of the report (October 19th) the general health was better than on any previous occasion, in spite of numerous causes of insalubrity. The average death-rate for the months of July, August, and September, was 20 per 1,000; the ordinary death-rate of Montevideo and Buenos Ayres being 30, and that of Rio de Janeiro 21.5 per 1,000. He then takes the opportunity of giving his government a lesson on the neglect of sanitary measures. "Granting," he says, "that the city presents a better sanitary aspect than in previous epochs, it does not follow that we should cease to consider the urgent necessity which exists for various provisions and improvements, of the highest importance to the public health. . . . The terrible epidemics of which we have been the victims have afforded us opportunities of carrying out improvements for the protection of the public health; but, by a cruel fatality, we preserve almost the same faults, the same defects, and the routine which we inherit from our forefathers. In the matter of building, for example, we proceed on a regular fixed plan, forgetting, in the construction of both public and private dwellings, the precepts and the most simple rules of sanitary science." The author of the report supports his statements by referring to the reports of the English Registrar-General on the influence of cubic space on mortality; and concludes with an urgent appeal to the Vice-President of the Province to carry out sanitary reforms, seeing that the country has already been

subjected to grievous epidemic ravages, and that cholera, which is prevailing in some parts of Europe, may visit its shores.

#### THE CHARITY ORGANISATION SOCIETY.

AT the meeting of the Medical Committee on Saturday last, at which several of the medical officers of free dispensaries were present by invitation, a strong feeling was expressed in favour of extending the provident principle. In the course of the discussion it was mentioned that it has been determined to convert the Notting Hill and Shepherd's Bush Dispensary into a provident institution. We understand that, at the conference which is to be held at the house of the Society of Arts on Tuesday next, at 3 P.M., in addition to Mr. W. H. Smith, M.P., the Chairman, and Mr. Stansfeld, the President of the Local Government Board (whom we mentioned last week), it is expected that the Earl of Lichfield, Sir Charles Trevelyan, Mr. Kennaway, M.P., Mr. Fowler, M.P., Mr. Randolph Robinson, Dr. Acland, Dr. Sibson, Dr. Fuller, Dr. James E. Pollock, Dr. John Ogle, Mr. Charles Hawkins, Mr. Holmes, and many others, will be present. The conference has been called to consider the best methods of checking the abuses now incidental to out-patient hospital relief, with special reference to the expediency of extending the provident principle; and we are requested to mention that it is open to all ladies or gentlemen interested in the subject.

#### CAMBRIDGE PHILOSOPHICAL SOCIETY.

THE annual dinner of the Cambridge Philosophical Society was held on Saturday evening in the hall of Jesus College. Dr. Humphry, the President, was in the chair, and was supported by a distinguished company. In addition to the members of the Society, the Earl of Kintore, the Presidents of the Royal Colleges of Physicians and Surgeons, Professors Huxley and Williamson, and Dr. Carpenter, were present. Dr. Humphry, in proposing "Prosperity to the Cambridge Philosophical Society," remarked that it was in a flourishing condition, and pointed out its importance as a means of promoting original research, especially among the younger members of the University. The Master of St. Peter's College proposed the toast of "The Presidents of the Colleges of Physicians and Surgeons," which was duly responded to, both these gentlemen expressing their satisfaction at the steps taken by the University in medical study, and their willingness to co-operate in joining heartily in any scheme such as a joint board of the University and other licensing bodies. Professor Huxley, in proposing "The University," complimented them upon the advance they had made in natural science. The Vice-Chancellor responded.

## SCOTLAND.

SIR ROBERT CHRISTISON, President of the Royal Society of Scotland, opened the first ordinary meeting of the present session on Monday evening last with an address on the Fresh Waters of Scotland.

#### ABERDEEN ROYAL INFIRMARY.

DR. HARVEY has resigned the appointment of Physician to the Aberdeen Infirmary after a long term of useful service; and has been elected consulting physician. We understand that several candidates are likely to present themselves for the vacant office. It has been resolved, for some reason not stated, that the vacancy shall not be advertised.

#### UNIVERSITY OF EDINBURGH: LADY STUDENTS.

AT the meeting of the University Court on the 1st instant, three resolutions were come to regarding the lady medical students. The first was to take the appeal against the decision of the Senatus as to rescinding the regulations for the education of women in medicine into consideration, at a meeting to be held on the 21st December. The second was not to consider the memorial submitted by Miss Jex Blake and other documents connected therewith, until after the above appeal has been

decided. The third was that if, through misapprehension of the University regulations, mixed classes have been held outside the University, these classes should be viewed as exceptional, and attendance on them considered as equivalent to attendance on separate classes.

#### CONVALESCENT HOSPITAL FOR DUNDEE.

A MUNIFICENT offer has just been made by Sir David Baxter, and it has, of course, been accepted. He has intimated his intention of erecting and completely endowing a convalescent hospital for his native town, Dundee, for which he has already done so much in public gifts. The new hospital will be in connection with the Infirmary, and will contain fifty to sixty beds. The hospital will be open not only to infirm convalescents, but to others from the town. A committee has been appointed to carry out Sir David's object, and building operations will be commenced as soon as possible.

#### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE following office-bearers for the ensuing year were elected on November 30th. *President:* R. Paterson, M.D. *Vice-President:* A. H. Douglas, M.D. *Council:* R. B. Malcolm, M.D.; Alexander Wood, M.D.; W. H. Lowe, M.D.; J. M. Duncan, M.D.; W. Sanders, M.D. *Examiners:* Drs. Begg, Alexander Wood, Douglas, Paterson, Wright, Keiller, Pattison, Cumming, Duncan, Haldane, G. W. Balfour, Struthers, Ritchie, Stewart, Linton, Muirhead, A. Macdonald, and Frazer. *Treasurer:* S. Somerville, M.D. *Secretary:* D. R. Haldane, M.D. *Curator of Museum:* T. R. Fraser, M.D.

### SPECIAL REPORT ON THE SANITARY STATE OF SCARBOROUGH.

FAVOURÉD by a letter from Lord Londesborough authorising his employés and requesting Mr. Dale to assist the gentleman whom we commissioned to undertake the inquiry, we have commenced an investigation, as careful and complete as the circumstances will admit, which includes an examination of the system of drainage and sanitary arrangement of Londesborough Lodge, an investigation of local cesspool nuisances, and a general survey of some of the zymotic diseases in Scarborough, and of causes likely to affect this class of diseases.

Londesborough Lodge is situated on the south side of the town of Scarborough, on an elevated position on the slope to the north side of the Valley Road. It is placed about midway between the Ramsdale Valley and Cliff Bridges, and faces, at a distance of about three hundred yards, the beautiful reach of sands over which the sea comes rolling in. The Lodge is skirted on the north side by the Villa Road; and still further up the slope are The Crescent and Belvoir Terrace; the rather extensive grounds of the Lodge run down at a steep incline to the Valley Road.

Londesborough Lodge is, we were informed, built on clay; the original part of the building is about thirty years old, and was constructed without cellars. Eighteen or twenty years ago an addition was made to the house, and at that time the entire building was cellared. The house consists of a ground floor and first floor, with cellars and other rooms on the basement. We shall presently allude to the system of sewerage adopted at the Lodge; but, before doing so, we shall try shortly to explain the drainage of the locality.

There are, then, two sewers which drain the immediate locality of the Lodge. One is for the Belvoir Terrace houses on the elevated ground above the Lodge, which is again a continuation of that from the locality immediately above. This sewer runs eastwards towards Faulkner Road, where it is joined by several others from houses to the north. It then runs down the Faulkner Road, about a hundred yards to the east of the Lodge, towards the Valley Road. The other drain carries the sewage from the houses in The Crescent, which is a continuation, to the north-west of Belvoir Terrace. This sewer sweeps round the face of the decline towards the Valley Road, through the grounds of Londesborough Lodge, about forty yards beneath the house. This sewer in its course receives the sewage from Londesborough Lodge and one or two neighbouring houses. These two sewers meet in the valley, and, after receiving the drainage from St. Nicholas Cliff, further to the east, form, at the Cliff Bridge, the main sewer in the Valley Road. A little below the bridge, the sewer drain-

ing the Ramsdale Hill houses, on the north side of the valley, unites with this. The common sewer thus formed is carried along the south sands to a point below the "Castle Rock," where it empties its contents in deep water. The pressure on this sewer is at high tides very great, and we are informed dams up its contents to a considerable height. Into the Valley Road common sewer a rivulet, running down the valley from the "Mere," some high ground outside the town, has been conducted for the purpose of flushing the sewer. The volume of water of this brook varies considerably, but is at times large, and during the rise of the tide would tend rapidly to fill the sewer. We were unable to ascertain that ventilating shafts existed in the sewers in connection with Londesborough Lodge.

The sewerage system of Londesborough Lodge in connection with the town sewers is shortly as follows. There are two cesspools situated in the basement of the house, the overflow from which escapes from the house into the drains which join the common sewer of the district, viz., the Valley Road sewer, which has been just described. There are altogether thirteen communications by means of water-closets and sinks between these cesspools and different parts of the house. Into the smaller of these cesspools, one water-closet on the ground floor of the Lodge, and several sinks communicate; into the larger, the sewage of the remaining closets, five in number, and the majority of the sinks, flows.

The water-closets and sinks leading to the cesspools are in all cases trapped in one or other of the ordinary ways; and during our investigation additional traps were being put on in order, we were told, to diminish as much as possible the entrance of foul air from the sewers into the house. Any great back pressure in the sewers would, however, still result in the escape of foul air forced through the traps; and this was admitted by the contractor who accompanied us in our investigation.

The smaller of the two cesspools had been opened and repaired with good results last year in consequence of complaints of bad smells; and again, since the illness of His Royal Highness, when it was found in good condition. The other cesspool had not been examined or emptied for some years so far as we were able to discover. The drains leading to and from the cesspool had, however, been examined within the past few days, and been found in good condition. A syphon trap had just been laid on between the sewers and both cesspools.

Attached to the bedroom occupied by his Royal Highness is a water-closet, supplied with a large window opening on the lawn. This closet, however, affords no means of through ventilation except into the bedroom. It was not offensive at our visit. About ten feet below the closet and under the basement-floor the larger cesspool is situated, and between the closet and cesspool a pipe directly communicates. The other closets open out into the passages in different parts of the Lodge. In consequence of the limited space in the house, the means of ventilating are in several instances defective. Means were being taken, however, for improving their present state. New and more commodious and "improved" pans were being in some instances put in to replace those in use.

We have thus a building, not of modern construction and difficult of ventilation, with two cesspools within its walls, one of which has apparently not been examined for years. Connected with these, are as many as thirteen pipes, trapped in the ordinary way, and communicating with all parts of the house. The cesspools, again, are connected with a system of common sewers subjected to pressure from the sea and the "Mere" brook, to such an extent, indeed, that, as we learn, they are sometimes dammed up high above the sea-level. The chances to Londesborough Lodge of fever infection, notwithstanding the great precautions adopted by Lord Londesborough, are thus rendered very considerable, for of course the traps, such as those used here and commonly, are by no means sufficient to resist anything like the pressure in the sewers of the Lodge. The house, therefore, is likely, from the numerous communications with the cesspools, to suffer from the reflux of sewer-gas. If, in addition to this, the common sewers become the receptacle for the *dejecta* of typhoid patients, the chances of mischief are largely increased; and, indeed, we have received information to the effect that typhoid fever has been recently by no means absent from the houses in Ramsdale Hill district, which contribute their sewage to the common sewer of Londesborough Lodge district.

We have already given in a previous number, and we give now in another column, particulars which will show that the whole of the Scarborough party was affected by some poison which produced illnesses of a diarrhoeal character, attended with other characteristic symptoms of sewage-poisoning; and that, out of a limited number of adults, as many as four starting from this one centre and going to different parts of the country, were struck down with typhoid fever after periods corresponding to the usual variations of the time of incubation.

It has been urged that the children and others who had for some time been residing at the Lodge, did not suffer. This, however, is so perfectly in accordance with a long series of observations as to the greater liability of new comers, that we need not dwell upon the subject further than to refer to the excellent section which Dr. Murchison has devoted to it in his treatise on *Continued Fevers*. Nor, of course, can we omit to reflect on the comparative rarity of typhoid attacking so many adults of one party, except there be some common cause in operation.

Mr. Dale's communication to the papers during the week has led to an impression, which he wishes us to correct, that he was cognisant of the existence of bad smells in the Lodge. We have received, however, other evidence of their presence. The certificate of the architects which has been published, whilst alluding to the existence of cesspools, omitted to mention that they were in the basement of the house itself, and described them as being in a perfectly satisfactory condition. Only one of them, however, was, as we have said, opened; and that was not the one connected with the five out of the six closets, and which had a close and immediate connection with the closet opening into the Prince's bed-chamber. Possibly, this examination will now be made. Such a cesspool is an obvious and pressing source of danger; and we do not well see how that danger can be obviated otherwise than by thoroughly ventilating the cesspool by a shaft carried above the elevation of the house, or, better still, by doing away with it altogether. It is impossible to divine the use of domestic cesspools in connection with an efficient system of sewerage, except it be to breed disease and propagate fever.

The result of our examination of the general system of sewerage in Scarborough is as follows.

Scarborough may in this respect be divided into the north and south parts. As to the south part, we take the following summary from a brief statement which Dr. J. W. Taylor, medical officer to the Local Board, has been so kind as to furnish to us.

"The main sewer in this town contains nine ventilators. The shaft leading down to each is four feet by three feet in diameter, and contains a screen of charcoal for the noxious gas to pass through. This charcoal is renewed, in the summer months, every month, and in the winter not quite so often. Every street in the town is thoroughly well drained, and all the sewage from the south side is conveyed by the main sewer into the sea, at the foot of the Castle Rock. The plans for this sewerage were prepared by the borough surveyor, and approved by Mr. Ranger, C.E., who was sent down by Government in the year 1862. These ventilators open out upon the level of the main streets."

A medical correspondent resident in Scarborough writes as follows. "Scarborough (*i. e.*, the old town, adjacent to Londesborough Lodge) is not only the worst drained town in England; it is simply not drained at all—a mass of middens, and ash-holes, and stinks, very few even of these filthy holes. We want the Health of Towns Act; we have only a pseudo Local Board, acting under a highly economical Council. The south side is water-closeted, but very carelessly so, as Mr. Dale's letter on diarrhoea states. Moreover, the royal party were shooting for days from Ayton to Willoughby on low black swampy land, over five miles of drains. Ayton, two years ago, was pregnant with typhoid fever; old Scarborough has this summer never been free from low fever and small-pox."

Another medical practitioner resident in the town, and excellently well informed, as we have reason to believe, upon this subject, states—"The spread of zymotic diseases here undoubtedly demands a strict inquiry. Since the appearance of your last article calling attention to the subject, we have sent a petition to the Secretary of the Home Department to beg that the Commissioners of the Privy Council Office be sent down to investigate the sanitary condition of this place."

It has been pointed out to us that the mortality of the north part of the town is much greater than that of the south; and that, in drawing up the returns, the Registrar should be required to show which districts have bad sanitary arrangements.

We personally visited some of the worst districts of the town. Very strong language indeed would not be misemployed in describing the foulness of some of the sanitary arrangements. Some of the worst evils of the cesspit system are present. We made the following note after visiting one street, which is not by any means the worst or oldest. "Houses better, but in some of them no water laid on. The pumps, supplied by water from surface-well, evidently largely polluted with cesspool matters, turbid and smelling badly. The rent of some rooms in these houses, the residents stated, had recently been raised threepence per week, on the understanding that the town-water was to be supplied. This has, however, not been done. They have to go a long way off for a supply of drinkable water. They thought the children sometimes drank the pump-water; and in one house typhoid fever had existed."

We are informed, on good authority, that in some of the worst districts ashpits used as privies exist within the houses, sometimes even

in the living-room. Of this we have no personal knowledge; and it seems scarcely credible. On the edge of the town, on the Seamer Road, within half a mile of Londesborough Lodge, and on the route of the Royal party to their shooting ground, a huge town-midden constitutes an offensive nuisance, of which the stench spreads widely, and which has been the subject of frequent complaint.

As to the water-supply of the town, which is also that of Londesborough Lodge, it has been publicly stated to be pure and excellent. The information which we have thus far of the result of microscopic examination is not altogether favourable; but we are unwilling to make a hasty report on this subject, and shall reserve a fuller statement of its examination for next week. As Mr. Dale has already stated, the royal party was supplied with bottled water from the hot springs of Bristol. This water has a high reputation for purity, and is much in favour for domestic use with the family at the Lodge. We are informed that it is put into the bottles hot; they are corked and sealed, and the water remains perfectly good for any number of years without sediment. The bottles of water which have been kindly furnished to us are of crystalline clearness and agreeable flavour. We have, however, received several communications on this subject; and one medical gentleman writes to us:—"I have strong reason for believing that it may prove the source of His Royal Highness's lamented illness—the spring from which this water is obtained being only a few feet from the river's brink, and being liable, at spring tides, to contamination from this source. I may explain that the whole sewage of Bristol is passed into the Avon considerably above this spring, and that the river is at times like an open sewer."

The chemical and other characters of the Bristol Hotwell waters are as follows; temperature 74 deg.; saline matters per pint 6 grains; viz., carbonate of lime, sulphate of lime, and sulphate of soda, each 1½ grains; chloride of sodium, 1 grain. We have placed samples of this water in the hands of Dr. Ferrier, that he may apply the zymotic test, with which he has had much experience while preparing his recent report for the Privy Council with Dr. Burdon Sanderson. The same test will be applied to the other waters.

It must, however, be remembered that only some of the members of the Royal party who suffered used this water; and that the *prima facie* evidence in its favour is very great, while the character of the rest of the facts seems to exclude it from the list of probable causes of this outbreak of typhoid fever. No other drinking-water than these was used, except aerated waters.

We cannot conclude this outline of the result of our labours without expressing our acknowledgments to Lord Londesborough, to the Dowager Duchess of Beaufort, to Lord Carnarvon, Mr. Dale, Mr. Peacock, Dr. Taylor, and others, who have given most ready and courteous assistance. Whatever may be the final conclusions, the greatest credit is evidently due to the Earl of Londesborough for the frank, honourable, and judicious course which he has pursued in favouring free inquiry into circumstances which have a national interest, although occurring within his private residence. The doubts raised must have been to him peculiarly painful; but there is no one who will not sympathise with that pain; and we desire to conclude this report with the expression of our conviction, that Lord Londesborough spared no pains nor expense to make the sanitary arrangements of his house perfect, and that he had every reason to believe that they were quite efficient. The thorough investigation which he has accepted at impartial hands has fully demonstrated this at least. It is no fault of his, that his intentions have apparently been frustrated by arrangements of which he could hardly be expected to appreciate the inefficiency. But his misfortune is likely to prove a great national lesson.

SIR RICHARD WALLACE, Bart., has given his name as a Vice-President to the Infirmary for Epilepsy and Paralysis, Charles Street; and at the same time he presented £200 to be added to the £2,000 fund which is being raised for the purpose of purchasing and furnishing new premises.

DONATIONS, BEQUESTS, ETC.—The following amounts have been given in reduction of the debt due to the Treasurer of the Bristol Royal Infirmary:—Mr. Wm. Frupp, £250; Mr. R. J. Pierce, £100; Mrs. Swann, £100; and Mr. S. S. Browne, £100.—Sir Richard Wallace, Bart., has given £200 to the Infirmary for Epilepsy and Paralysis.—Mr. W. H. Bracebridge, of Sherborne, has bequeathed £100 each to the Warneford General Bathing Institution and Leamington Hospital, the Buckingham Infirmary, and the Asylum for Idiots, Earlswood.—Sir Thomas Tilson has made his fifteenth donation of £50 to the Endowment Fund of St. Mark's Hospital for Fistula.—The Brighton and Hove Dispensary has received £100 (less duty) under the will of Miss Wilhelmina Hamilton.

## ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.

THE fifth anniversary session of this Association was held at the Freemasons' Tavern, Great Queen Street, on Friday and Saturday, the 1st and 2nd instant; HENRY DAY, M.D., of Stafford, President, in the Chair.

*Officers and Council.*—The following were elected for 1872. *President:* Deputy Inspector-General Dr. C. A. Gordon, C.B., Dover. *Vice-Presidents:* Dr. Crisp; Dr. Black, Chesterfield; Dr. Cholmeley; Dr. Wynn Williams; Dr. G. W. Balfour, Edinburgh; and Dr. Lush, M.P., Salisbury. *President of Council:* Dr. B. W. Richardson, F.R.S. *Council:* Dr. Thomas Ballard; Dr. Dudfield, Kensington; Dr. Day-Goss, Kennington; Dr. Cleveland; Dr. Buchanan, Glasgow; Dr. W. H. Day; Dr. J. T. Griffith, Camberwell; Dr. Wiltshire; Dr. Barnard Davis, F.R.S.; Shelton; Dr. Jencken, Dublin; Dr. Ross; Dr. Royston; Dr. G. Bird; Dr. Brewer, M.P.; Dr. Lockhart Clarke, F.R.S.; Dr. William Cooke; Dr. Wharton Hood; Dr. Murray Lindsay, Hanwell; Dr. Nicholls, Chelmsford; Dr. Semple; Dr. Stedman, Guildford; Dr. Christie, Royal India Asylum; Dr. Bower Harrison, Manchester; Dr. Samuel Hill; Dr. Humby; Dr. Lipscomb, St. Albans; Dr. Macdonald, R.N., F.R.S., Woolwich; Dr. Moon, Brighton; Dr. Norris, Birmingham; Dr. Painter, Brompton; and Dr. Waring. *Treasurer:* Dr. Paul, Camberwell. *Secretary:* Dr. L. W. Sedgwick, London.

*Presentation to Dr. Richardson.*—A gown and hood of the Doctor of Medicine were presented to Dr. Richardson, F.R.S., as a slight acknowledgment of the eminent services which he had rendered to the Association during his four years tenure of office as President.

*The Report of the Council* dwelt chiefly on the mode of taking medical evidence in courts of law, and on the regulations for the degree of M.D. The Council reported that they were taking steps to circulate largely, among non-graduates, a memorandum referring to the present limitation of the annual number of degrees conferred by the University; stating that the University has recently attempted to amend the regulations by substituting for the provision that the candidate shall be forty years of age, one requiring him to have been in possession for five years of a medical or surgical qualification which would entitle him to be registered under the Medical Act, and by abolishing the limitation in the number of degrees to be granted annually; but that the consent of Her Majesty the Queen in Council, which is needed to render any new regulation of this kind valid, has been refused, for the reason that no sufficient ground has been shown for any further extension of the privileges of the University.

"This Association has contended that the report of the Scottish University Commissioners as to the sufficiency of ten degrees annually (which has doubtless influenced the decision of the Privy Council) is based on untrustworthy authority; that these arbitrary limitations as to the age and number of the graduates exclude from the degree many candidates who by their position and acquirements are entitled to offer themselves for examination; and that the true and only limit to the number of degrees granted to already legally qualified medical practitioners of acknowledged respectability and position should be afforded by an extended and searching examination.

"Under these circumstances the Association is wishful to ascertain, as nearly as may be, the exact amount and nature of the injurious effect of the present regulations; and for this purpose it is endeavouring by means of a form, which it is hoped will be largely used and promptly returned, to collect the opinion of those most intimately concerned; the opinion, that is, of those legally qualified members of the profession who may now or in a short time desire to obtain the degree of Doctor of Medicine.

"The Association, pressed by various and conflicting opinions and statements concerning the matter in hand, is only anxious to determine on absolute facts what is the true professional requirement; it is not, therefore, intended to publish the names of those who are good enough to express in this manner their opinion on the subject, but merely to furnish the University Court, and, if necessary, the Privy Council, with accurate data."

*A Discussion on Habitual Drunkenness, and its Treatment, Medical and Legislative*, was introduced by Dr. Swete, and continued by Dr. Griffith, Dr. Richardson, F.R.S., Dr. Lush, M.P., Mr. Hepworth Dixon, Dr. Seaton, Dr. Crisp, Dr. Thomas Ballard, the President, and others. The majority of the speakers considered that, in any legislative enactment that might be considered desirable, a distinction should be drawn between drunkenness as a disease, and drunkenness as a crime; and that the former might well be treated under similar regulations to those provided by the Lunacy Acts. On the other hand, it was contended that dipsomania, if there were such a disease, had no recognisable character, and that the description given of it was vague

and unsatisfactory. Great sympathy with the efforts of Dr. Dalrymple was expressed, and the object he had in view was emphatically approved; but there was a general opinion that many modifications were necessary in the provisions of the Bill. A strong opinion in favour of legislation of this character was expressed by Mr. Hepworth Dixon as one outside of the profession, and he asserted his emphatic belief that there was a good in what might be called mechanical or mathematical legislation—a legislation of hard lines and rules, whereby a man might see for himself that he was outside a standard of right, and was branded as a wrong-doer. In a new path like this, many mistakes would no doubt be made at first, and watchful attention would be essential to good progress.

On the motion of Dr. RICHARDSON, seconded by Mr. HEPWORTH DIXON, it was unanimously resolved—"That the Council of this Association be requested to watch the progress of Dr. Dalrymple's Bill, and, at the proper time, to prepare an analysis of, and an opinion concerning, the probable working of the Bill; and that the Council be empowered to communicate the same to a public meeting of the profession at large and of the public, if the proceeding be considered advantageous."

*President's Address.*—On December 2nd, the President, Dr. H. DAY, delivered the anniversary address on the Historical Steps of Modern Medicine. He passed in review modern progress in Histology both healthy and morbid, in Animal Dialysis, in the study of disease by Synthesis, in the methods of Physical Diagnosis, in Surgical Operations, and concluded a most interesting address with some remarks on Therapeutics.

"Three remarkable progressions," he said, "seem to my mind to distinguish modern therapeutics. The first consists in the study of the action of medicines by the investigation of the physical characteristics of each medicinal substance; the second consists in distinguishing the special action of different remedial substances on particular parts of the living organism; and the third consists in bringing the art of prescribing to the utmost simplicity, so that when we prescribe we know precisely on what we wish to rely for the good we would secure. All these methods of improvement hang closely together, and yet they are often distinctly pursued, not only by different men, but by men of diverse modes of thought. They are all good and productive of the best influences. It would be incredible to our forefathers to hear that we have men now, who—if you give them a chemical substance and tell them, this substance is composed of the following elements, it is of this specific weight, it is of this reaction, it is of this solubility, and it has certain other physical qualities therewith named—will tell you, in return, with an absolutely near approximation to the truth, what will be the physiological action of the said substance. Yet this is an accomplished fact, and, in the matter of those agents we employ to relieve pain, it has been one of the most fruitful means of the development of the triumph of human art over human suffering; a development belonging truly to the whole Christian era, but most to this latter-day section of that marvellous testimony of 'the ways of God to man.'

"Equally strange would it be to our forefathers to hear that we can now predict where a medicine shall, to speak plainly, go into the organism, and on what it shall act. Yet, in the case of some of our most potent agents, such as arsenic, nitrite of amyl, woorari, we know, when we give them, what will be the seat in which their influence or force will be expended, as well as the nature or quality of that influence.

"Finally, to the most distinguished of the older prescribers how strange it would be to tell them, we give up that long list of agents that constituted your favourite formulæ; we are content to try one agent at one time; and as to your method of putting your medicines into the body by the stomach only, we, in our day, wise as serpents and gentle as doves, put them in by the skin if we like, with a sharp tooth, or instil them in vapour by the lungs so subtly, that the administration is all but unperceived. Yet this, too, is daily done, and with a successful result undreamed of by the earlier pilgrims of medical progress, and certain amongst the historical steps of our time to remain.

"I close the page. If any out-door friend asks of me, and many do ask, what do you of legitimate medicine more than homeopaths, or other schismatics, to advance medical science and medical art? I point such friends, as I point you, my colleagues, to the deeds of medicine I have related so feebly, so imperfectly, to day. I ask, in my turn, where would modern medicine have been if these things had not been achieved? And I affirm, honestly, that those who have achieved them, and none other, are the legitimate professors of the science and the art. To them I bow and declare renewed allegiance."

On the motion of Sir THOMAS WATSON, Bart., a cordial vote of thanks was offered to Dr. Day for his address.

In the evening the usual dinner took place.

# THE MEDICAL INSTITUTIONS AND PREVAILING DISEASES OF VICTORIA.

[FROM A SPECIAL CORRESPONDENT.]

## II.

**ASYLUMS OF VICTORIA.**—The YARRA BEND, the first, and still by far the largest of the asylums in Victoria, forms almost a village in itself, and is situated on one of the beautiful bends of the Yarra Yarra, three miles in a direct line from the centre of the city. Except that it lies somewhat low, its situation is unrivalled for beauty by that of any similar institution I have ever seen, and the numerous small cottages of which it consists are picturesquely embowered amid shrubs and evergreens, flowering plants, and creepers of all descriptions, while the river itself, flowing rapidly between its well wooded banks, embraces it on several sides in its windings. It has a very large extent of open ground belonging to it, granted by the Government—six or seven hundred acres, if I remember right—many of which are kept under culture as a vegetable garden by the patients.

It is built in two divisions—the upper and lower. The upper is the more recent, and is enclosed partly by a high brick wall on the outer side of a deep fosse, and partly by a zinc fence. It is used exclusively for the quieter class of male patients, and consists of a series of single-storeyed red brick cottages, standing each within a small garden plot. In front is a verandah, from which the day-room is entered. On each side of this sitting-room there are two sleeping apartments, each of which is meant to contain four patients, while a small room behind the day-room is used by the warder. Besides the cottages, there are three larger blocks in this division, each being quite separate from the others. The least of the three is only one-storeyed, and is used as a hospital, for which purpose it is tolerably well suited, the principal ward being built as a pavilion with a good cross-ventilation, though, owing to overhanging verandahs, it is not very well lighted. There are, besides, one or two isolated cells in the same block for refractory patients. The other two detached piles of building are larger and have two storeys, with the corridor running along nearly the whole length of each block, and parallel to the outer verandah. This corridor is used as the day-room, and it is cut into two equal halves by a warder's room, which has a window pierced in each wall so as to overlook each semi-division. From it open the isolated cells, most of which are lined only with wood, while a few are padded. At each end of the corridor there are bath-rooms, closets, etc., and a side-door leading into a sleeping-room designed for four patients, and projecting slightly beyond the verandah. The upper storeys are simply fac-similes of the lower.

The upper division, however, is not the only part of the asylum reserved for male patients; for, in the lower, there are confined, in one wooden and a couple of bluestone wards, nearly one hundred and twenty of the more violent patients, besides nearly all the criminal lunatics. The stone wards have long narrow rooms in their centres, with the dormitories and single cells opening off them on each side. Some of these latter are stone, others of wood, and only a very few are padded. Both wards are provided with a yard. The wooden ward, or shed—for it is little better—along with a similar one side by side for refractory female patients, are disgraces to civilisation. Their worm-eaten and rotten planks swarm with every kind of noxious insect, and the dormitories opening off the yard which encloses them have no provision at all for ventilation, except a few apertures in the walls. A couple of hours after the patients had retired for the night, it was sickening to enter these holes; but it is only right to say that they had long before been condemned by the medical inspector, as, apart from every other consideration, the slightest spark would set the whole place in a blaze, when its crowded wards could not fail to become the funeral pyres of most of the wretched occupants.

The female division in part consists of a series of small wooden chalets enclosed within a tolerably high fence, and very pleasing to the eye, standing, as they do, each in the centre of its own small garden, and covered, nearly from basement to summit, with clematis, passion-flowers, dolichos, and other creepers. Ten of these small cottages form an oblong, in the centre of which stands the wooden building, which answers the purpose of day- and sewing-room, chapel, and ball-room indiscriminately. Each cottage has a verandah in front, and is raised about a foot above the ground on wooden beams. The sitting-room is entered directly from the verandah, and on each side are the doors into the sleeping apartments, which are ridiculously small, though arranged for three patients, and rarely containing fewer than four. There cannot be said to be any ventilation in these cribs at all; a few apertures in the roof and above the windows being the only

attempt at establishing a through current. In fact, no architect could have contrived more effectually how not to ventilate; and in the hot and close summer nights these apartments, the shutters of which are necessarily kept closed to prevent escape, are simply asphyxiating. However much, then, we may admire the picturesque beauty of the cottages, or approve of the system, we cannot help expressing an earnest hope that the present wretchedly contrived huts may be left for as short a time as possible cumbering the ground. Two small wards, destined for female hospitals, and within the same enclosure, are thoroughly unsuited for this purpose; and the whole of the wooden buildings generally in this division cannot be too emphatically condemned. A few bluestone wards, near the enclosure just described, are reserved for the more noisy and violent female patients.

**THE KEW ASYLUM.**—Close to the Yarra Bend, but high above it, on an eminence commanding an admirable view in every direction, there has been in course of construction, for many years, an enormous pile of stuccoed brick building, which, when completed, will be “the asylum” of the colony. It was designed to hold over six hundred lunatics, and is entirely on the corridor system, the corridors being wide and spacious, and, in almost every case, intended for day-rooms. From the central block on the southern side of the asylum, built for administrative purposes solely, and apparently very handsome, though not quite completed at the date of my visit, there run two long wings, subdivided however by two small towers equidistant from the officers' quarters. At the spot at which these towers rise there run, at right angles to the long wings, two others; and within the three sides of the square thus formed, and connected with the wings only by covered passages, there stands a very handsome central hall, surmounted by a high tower, with unexceptionable billiard and reading rooms attached; and, so far as I am able to judge, an admirable kitchen, with all the most recent improvements for cooking, baking, and distributing the food.

There does not seem to be any very regular system of wards, some of the rooms having only one set of windows; and those looking into the verandah which runs along the inner side of the building, are rather dark and cheerless, while others which, from being situated at the corners of the wings, project considerably from the main pile, and thus have windows on three sides, are light and airy. The single cells are very numerous, and, in almost every instance, open off the corridor. Some of them are lined with wood, others only have their brickwalls oil-painted, while a few are delightfully white and pleasing to the eye, being covered with Kean's impermeable cement.\* The shutters in all these cells have the ordinary arrangement, being made to move up and down by the action of a catch in the outer wall; and, besides having a ventilator over the window, there is a small wire-covered opening into the corridor above the cell-door. The whole cost of this palatial asylum has been over £120,000; for it ought to be borne in mind that labour is nearly three times as expensive in Victoria as at home. It has been many years in the hands of different contractors, I believe, and, even when thoroughly complete, will obviously prove an anachronism in such a climate as that of Victoria, for the brick cottages I have described as forming a large portion of the upper division of the Yarra Bend Asylum, would, if constructed on a better system for ventilation, have not only answered all the purposes required of them admirably, but would admit of a simple method of classification, and of a more ready means of separating different patients—an inestimable boon to the unfortunates themselves; while the slightly increased expenses entailed on the government in administration, would have been far more than counterbalanced by the cheapness of erection.

There are two other large asylums in Victoria—the “Beechworth” and the “Ararat,” both of which have only been in use a few years. The Beechworth Asylum I did not visit, but it is not quite so large as the one at Ararat, which, though standing on a good situation, has had its effect as a building completely destroyed by the ruthless and barbarous fashion in which every sign of vegetation has been cleared away from its immediate neighbourhood. It is in construction nearly a fac-simile of the Kew Asylum which I have just described, although not nearly as large, as it would be crowded with four hundred patients. The present energetic superintendent, Dr. Robertson, keeps it in admirable order, and it is in every respect a model asylum. Besides these larger institutions for the treatment of the insane, there is another smaller building in Melbourne, called the “Stockade,” to which chiefly incurable lunatics are drafted from the Yarra Bend; and there is one small private lunatic asylum in Melbourne, which, though the only one in the colony, has but very few patients.†

\* A very expensive compound, however; as it costs, I was told, five shillings per square yard.

† The proportion of lunatics to the entire population is very much the same as in Victoria and in England; but some statistics I expect on the subject have not yet arrived.

**CORONERS' INQUESTS, AND NECROPSIES AT THE YARRA BEND ASYLUM.**—Strange as it may appear to the profession in this country, it is yet a fact that in Victoria, since the year 1865, a coroner's inquest has been held in every instance of the death of a patient in the Yarra Bend Asylum, quite irrespectively of the fact of the death having occurred under suspicious circumstances. It is clear, then, that, so far, the lunatics in Melbourne are quite as favoured a class of the community of Victoria as our own gaol-birds at home; as, in the case of anyone dying sane in mind, it is not thought at all necessary to inquire so particularly into the cause.

What those inquests imply is evident; a supreme distrust of the professional men the Government appoint to inspect and superintend the asylums of the colony, and an equally strong want of faith in the treatment of the medical men and attendants. Indeed, this absence of confidence in their own officers is, I am told, the only alleged reason for the necessity of holding such inquests at all. It is stated, although there is contradictory evidence on the subject, that some years ago grave and serious abuses were discovered in the only asylum then existing—the Yarra Bend; that, after a long inquiry into the alleged abuses, the superintendent at that time was dismissed, and the Coroners Statute Act so amended as to necessitate the holding of inquests in all cases of death in lunatic asylums throughout the colony. A new inspector was appointed, and a gentleman eminently qualified for discharging the duties of such an office, came out from England to discover that he was placed in the anomalous position of being considered worthy to occupy a post of serious responsibility, and yet find himself thoroughly snubbed by the absolute want of confidence in his judgment and integrity, which those inquests implied. This curious anomaly never seems to have struck the Victorians at all; and for the last five years, I am credibly informed, those inquests have been held at a great expense\* to the colony, and with completely negative results, so far as the discovery of any particular abuses is concerned.†

It thus appears that, on account of one black sheep, all the members of the profession, who devote themselves to the study of lunacy in Victoria, find themselves in the strangely humiliating position of being appointed by the Government to look after and treat the lunatics of the colony, and then of having themselves suspected of maltreatment, in every case which ends fatally, by the very men who appoint them; and of being subjected to the degrading necessity of justifying their own treatment and that of their subordinates before a coroner and his jury-men. If the colonists can go on throwing away money in this remarkable fashion, one might readily fancy that Victoria had already become the earthly paradise which the term *Australia Felix* was used to express, and that there were absolutely no abuses to be remedied, no crying disgraces to be removed, in this land of gold and universal happiness. Have the unfortunate paupers in the Benevolent Asylum such admirable quarters? Do not the principal streets of Melbourne convey to the eyes and noses of travellers such sights and odours as are not even to be found in the lowest slums of London? and do not hundreds of infants yearly fall victims to the want of proper sanitary arrangements in that handsome city, which might easily be made the healthiest on the globe? Or even, to strike more directly home, can the thousand lunatics in the Yarra Bend be properly looked after by two medical men? When their country is thoroughly opened up by roads and railways, when there is a good system of irrigation, and when sufficient encouragement is given to immigrants, let the Victorians, if they find they have still money to throw away, after attending to those and a thousand other crying wants, indulge their pseudo-sentimentalism on the subject of pauper lunatics to their hearts' content, and enforce an inquest on every patient who dies in a lunatic Asylum.

Although to my mind, however, the insult to our profession, implied in these coroners' inquests, is sufficiently great, the council of the colony has yet contrived to make them even more insulting to the officers of these asylums, by appointing, in every case, extraneous medical men to perform the necropsies. What would professional men at home say, if, after having treated a patient to the end, they were not only forbidden to make the *post mortem* examination, but not even asked to be present at it? And what must we think of the accuracy of the verdict when the jury have to depend for the cause of death on the evidence of the pathologist alone? As soon as a patient dies in one of the asylums the coroner is informed of the fact, and he sends an order for an examination of the body to one of the staff of medical men in town appointed for this purpose. The asylum physician has, of course, merely to draw up his evidence on the signs and symptoms which he has observed during the patient's life, and, until the inquest, he is in distressing

ignorance as to whether any fact or facts, unnoticed by him, are to be brought out by the pathologist's evidence, and held *in terrorem* over him. When the two statements are taken, the result is, of course, in many cases conflicting; the medical officer judging from the symptoms which he has observed, and ascribing the death in many instances to an entirely different cause from the pathologist, who, it must be recollected, has never seen the patient in life. To show what inevitable discrepancies must arise in this way, it may be sufficient to cite a couple of instances. Thus in one woman, whose death was caused by exhaustion from the discharge of an enormous quantity of foetid pus from a large carbuncle, which had become a bed sore, the coroner's verdict returned it as resulting from disease of the brain, in accordance with the evidence of the pathologist, who very naturally ascribed it to what he regarded as the most important organic lesion; while, in another, the verdict was "death from hydatids," whereas, in reality, the hydatids of the liver and omentum which existed, had almost nothing whatever to do with the fatal issue, which was due to the exhaustion produced by very violent maniacal excitement in an enfeebled woman. In this last case the efforts of the jurymen, in their conscientious attempts to understand the true nature of hydatids, were highly praiseworthy, though the questions they put were supremely ridiculous. Of course, in those instances, the nature of the verdict was of no moment; but it is obvious that it would be easy for the pathologist to make a very grave mistake, supposing the medical men and attendants had some motive for garbling their evidence. Thus, if a lunatic had been poisoned by morphia, by strychnia, or had died even in many other ways, there would be so little to excite the pathologist's attention that, in nine such cases out of ten, he would be compelled simply to ascribe the death to the most prominent visceral lesion.

I need scarcely point out that the physicians to the asylums, thus finding themselves deprived of the opportunity of following up their cases after death, must lose, to a great extent, any interest in very accurate diagnosis; and even if they conscientiously treat the patients to the last, as I am firmly persuaded those gentlemen do, they must feel themselves balked and disappointed in their inquiries by the wretched obstacles the Government has thrown in their way; and, as a matter of course, however energetic or able they may be, we can scarcely expect to see psychological science make any very great advances in the colony of Victoria.

The truth is, that the inspector or superintendent is the proper official to look after the asylum in all respects. The appointment of men whom their Government cannot trust is surely too great an anomaly even for Victorians. If it were a rule that all cases of sudden death, or death from epilepsy, accident, or suicide, or under any suspicious circumstances, were to be investigated, and that an occasional inquest was to be held at the option of the inspector or coroner, the ends of justice would not only be fully as well attained, but the colony would be spared a large and unprofitable expenditure.

THE BALLARAT DISTRICT HOSPITAL, next to that of Melbourne much the largest general hospital in the colony, occupies a very pleasing situation in Ballarat, in the midst of pretty grounds, well-ornamented with shrubs and flowers; and, up to the present time at least, it has plenty of vacant space around it. As the oldest part dates as far back as 1855, it is, as a matter of course, on the corridor system, and in consequence very inadequately represents the present stage of improvement in hospital construction. The ventilation is necessarily imperfect, as a few perforated zinc plates, and a glass slide above the corridor, are the only attempts made at establishing a through current. The amount of cubic space to each patient in this part of the building is 1450 cubic feet. The second ward was more recently erected, and was so far a pavilion ward that there were opposite windows on two sides, with fireplaces at each end, and a couple of windows besides in the wall facing the door. It was a light, cheerful, and airy ward, the ventilators in the roof communicating with the outer air below the flooring of the second storey. Unfortunately the closets opened immediately off one of the side walls of the ward.

In connection with the visit of Prince Alfred to Ballarat, in 1867, the necessary funds were raised to erect an extra wing, which stands completely detached, and faces in the opposite direction to the main building. It is built in three storeys, and slopes in the opposite direction, so, as the ceilings are very high, it towers over the rest of the hospital in rather an ungainly fashion. The wards are, however, excellent, with so many windows that, on three sides, the walls seem literally made of glass, especially as the windows reach nearly to the roof from a couple of feet above the level of the beds. The wards are all entered from a side tower, which, besides the staircase, is intended to contain a hydraulic lift for the convenience of the patients. At the further end of the ward, from the tower entrance, there is a central apartment for the attendant, screened off by a glass partition, and to the right and left of

\* Each inquest, with its concomitant *post mortem* examination, must cost over £7.

† The statute is strictly attended to in Melbourne, where the influence of the lower classes is greatly dreaded by the government. In at least one asylum in the colony, however, the inquests are only held at the discretion of the coroner.

this the closets, and a bath and pantry-room. There are earth-closets, on a Melbourne patent, said never to work. Each of those wards is intended for twenty-five patients, and the cubic space must be ample, though I unfortunately neglected to obtain the exact measurements. The lowest ward is as yet the only one in use.

[To be continued.]

## ASSOCIATION INTELLIGENCE.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

A MEETING of this Branch will be held in the Theatre of the Midland Institute, Birmingham, on Thursday, December 14th, at 3 P.M.

A meeting of the Council of the Branch will be held in the same place at 2.30 P.M.

On the same day, and in the same place, the Committee appointed by the Branch for making arrangements for the annual meeting of the British Medical Association, will meet immediately after the Branch meeting.

T. H. BARTLEET, *Honorary Secretary*.

Birmingham, November 26th, 1871.

### BATH AND BRISTOL BRANCH.

THE second ordinary meeting of the above Branch will be held at the College Green Hotel, Bristol, on Thursday, December 14th, at seven o'clock: CROSBY LEONARD, Esq., President, in the Chair.

R. S. FOWLER, Bath, } *Honorary Secretaries*.  
E. C. BOARD, Clifton, }

Bristol, December 1871.

### SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEDICAL MEETINGS.

THE next meeting of the above Society will be held at the Greyhound Hotel, Croydon, on Thursday, December 21st: Dr. COLES will take the Chair at 4 P.M.

The dinner will take place at 6 P.M.

Papers, etc., are promised by Mr. S. Lee Rymer, Dr. Jeaffreson, the Chairman, etc.

HENRY T. LANCHESTER, M.D., *Honorary Secretary*.

Croydon, December 6th, 1871.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE forty-second meeting was held at the Fountain Hotel, Canterbury, on Thursday, November 23rd, at 3 P.M.

*Papers.*—The following papers were read.

1. Rupture of Aorta within the Pericardium. By B. Browning, Esq. (See page 661).

2. Cases of Variola during the latter months of Pregnancy and at Delivery, with the Results. By G. Rigden, Esq. The author read an abstract of five cases of variola occurring in women during the latter months of their pregnancy; and two cases of the disease existing in the mother at the time of delivery at the full term, in which it seemed so little to affect their offspring, that they were not only born at the full term without any evidence of the disease having affected them, but were in all the cases susceptible to the influence of vaccination at ages varying from three to six months. Three other cases were reported of females suffering from the disease in the earlier months of their pregnancy, in which the embryo did not appear to be affected, but there had been no opportunity of tracing the mothers to their time of delivery, and consequently it had not been possible to ascertain their susceptibility to vaccination.

3. Hernia, with Cases of Operation for Strangulation. By R. Hicks, Esq.

4. Remarks on the Diagnosis and Surgical Treatment of Fibroid Tumours of the Uterus. By Alfred Meadows, M.D.

The members afterwards dined together.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEETING.

A MEETING of this district society was held on November 24th, at the Old Ship Hotel, Brighton; ALFRED HALL, M.D., in the Chair. Twenty-six members and two visitors were present.

*Communications.*—I. THE PRESIDENT related a case of Mechanical Dysmenorrhœa and Chronic Endometritis. (See p. 667.)

2. Mr. J. JARDINE MURRAY exhibited an instrument invented by Mr. Spencer Wells for Tapping in Ascites. Opinions were much divided respecting its merits.

3. Dr. ORMEROD showed a Fractured Humerus from a young Horse four years old, caused by muscular action. Under the microscope, the bone-cells showed no canaliculi; there was a general infiltration of fat, but no fatty degeneration. Several members present mentioned cases of fracture from muscular action which had occurred in their experience, both in the human subject and also in horses.

4. Mr. J. JARDINE MURRAY read a paper on the Danger of Ill-constructed and Neglected Cisterns, which time would not permit of discussing.

*Dinner.*—Twenty-one members and two visitors subsequently dined together at the Old Ship, under the presidency of Dr. A. Hall.

The next District Meeting will be held at Lewes, in March 1872; Mr. R. Turner in the Chair. Communications will be thankfully received by the Honorary Secretary, Dr. Trollope, St. Leonard's-on-Sea.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE second meeting of the session 1871-2, was held at Maidstone on November 28th; ALBERT DAVIES, M.D., in the Chair.

The Next Meeting was appointed to be held at Gravesend in March.

The election of a member of the Medico-Ethical Committee, *vice* Joy, was deferred.

*New Members.*—The following were elected:—Samuel Prall, M.D., West Malling; John W. Fry, Esq., Waterbury.

*Resolutions.*—I. It was resolved—"That the Honorary Secretary shall use open circulars for convening the district meetings (as lately practised tentatively)."

2. It was resolved—"That the members of this district recommend the Branch Secretary to apply for arrears by closed letter."

*Communications.*—I. A Case of Concussion of the Brain. By Charles E. Hoar, Esq. A young gentleman, aged 23, sustained a severe concussion of the brain from being thrown out of a dog-cart. No bones were broken. There was no paralysis. Unconsciousness existed without stertor. The pulse was very slow, the upper lid of the left eye dropped, and other symptoms of paralysis of the third nerve were present. Ophthalmoscopic examination discovered no intraocular lesion. The patient gradually recovered, and after three months is able to use his left eye. He cannot, however, read for a long period. Mr. Hoar considered the paralysis of the third nerve to have been caused by a small effusion of blood at the back of the orbit. The slow pulse of 40 to 50 he attributed to shock.

2. Two patients were exhibited by Mr. M. Adams, suffering from Intraocular Tumour; viz. (a), fibrous tumour of iris; (b) sarcomatous tumour.

*Dinner.*—The members and visitors dined at the Mitre Hotel.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

*Hip-Disease.*—*Laryngeal Changes.*—*Tubercular Meningitis.*—*Mitral Stenosis.*—*Aortic Aneurism.*—*Facitious Urticaria.*—*Patency of Foramen Ovale.*—*Fracture of Neck of Scapula.*

THE second ordinary meeting of the session was held on November 24th. Present: ALFRED BAKER, Esq., in the Chair, and thirty-two members.

1. Mr. FURNEAUX JORDAN showed a specimen of Hip-disease in an early stage, undergoing repair. It was removed from a young man who died, while under treatment, from meningitis. The capsule was distended with liquid. The ligaments, synovial membrane (save slight thickening and vascularity), and cartilages, were little altered. The ligamentum teres was healthy. The epiphyseal lines of cartilage were distinctly seen on section. The bone generally presented the appearance of sclerosis. The epiphyses were little diseased, the principal pathological change being in the extremity of the diaphysis.

2. Dr. SAWYER exhibited two specimens of Phthisical Ulceration of the Larynx. He also showed sketches of the laryngoscopic appearances in two cases of unilateral paralysis of the adductors of the vocal chords.

3. Dr. UNDERHILL showed two specimens of Tubercular Meningitis. In the first case, that of a boy aged 10, the symptoms were of about eight months' duration, commencing with typhoid symptoms. There were large cheesy deposits in the cerebellum, with meningitis and miliary tubercle at the base of the brain, cheesy deposits in the

bronchial and mesenteric glands, and general tuberculosis. In the second case, that of a boy aged 9, the symptoms seemed to date from an injury to the head received three years previously. There were found cheesy deposits in the cerebellum and meningitis of the base, but no miliary tubercle. There was also general tuberculosis. He also showed the temperature-charts of these and similar cases which had come under his notice at the Children's Hospital, briefly narrating their histories and *post mortem* appearances.

4. Dr. WELCH showed the Heart removed from a woman aged 54, who died of general dropsy. There were adherent pericardium, narrowing of the mitral orifice, with thickening of the mitral valves and tendons, thickening and bulging of the aortic valves. A small aneurism, of the size of a large pea, also projected from the left into the right auricle, at the site of the valve closing the foramen ovale.

5. Dr. WELCH also exhibited an Aneurism of the ascending and transverse portion of the Arch of the Aorta, perforating the left side of the sternum and the intercostal muscles between the first and second and the second and third ribs, and rupturing externally. Within the chest, the aneurism extended from the aortic orifice to just below the origin of the left subclavian artery. The walls of this part of the aneurism were formed by the dilatation of the coats of the aorta until it came into contact with the sternum and ribs; then the arterial coats disappeared, and the walls consisted of thickened pleura and cellular tissue. Outside the chest, the aneurism extended from the left axilla to the right of the sternum, and from the first to the fifth rib, forming a large pea-shaped tumour, which had ruptured over the sternum opposite the third costal cartilage. The wall of this portion was formed by the pectoral muscles and skin. The specimen was taken from a man aged 62, a nailmaker, formerly a soldier. He was admitted into the General Hospital four months ago, under the care of Dr. Bell Fletcher, the aneurism being then not larger than a hen's egg outside the chest. There was never any *bruit* to be heard over the aneurism; and the heart's sounds were normal.

6. Dr. RUSSELL brought forward a case of Factitious Urticaria, and remarked that it had considerable interest in relation to the ordinary forms of urticaria, and supported the general opinion of dermatologists that in its origin the disease was a neurosis. The phenomena of the common forms of urticaria all pointed to this conclusion. The stinging and itching which ordinarily attended the eruption, and the perversion of tactile sensibility when the disease affected the hands and fingers; the febrile prodromata, the vertigo and nausea, the constricted throat and peculiar cough which accompanied severe forms of urticaria febrilis and urticaria *ab ingestis*, all indicated altered innervation. The remarkably fugitive and erratic nature of the wheals, their sudden production, brief duration, and speedy reappearance in some other part, were most satisfactorily explained on the hypothesis of their nervous origin. The usual causes of the eruption indicated direct or reflex irritation of the contractile tissues of the skin. Wilson alleges, "irritation of the gastro-pulmonary or genito-urinary mucous membrane as the most common cause; and the peculiar nature of many of the substances which give rise to urticaria, when introduced into the digestive canal," seemed to point to an anomalous state of nerve-function in the particular individual. As to direct irritation, many cases approached closely to the factitious form; the sting of the nettle, the bite of certain insects, the bug, the gnat, certain species of mites in fruit (Hebra), even simple scratching—especially when certain other forms of eruption were present—all these acted most probably on nerve-tissue. Mental excitement was pointedly adduced both by Hebra and Wilson, and the former spoke of urticaria as being occasionally caused by the ague poison. Opium and belladonna were neurotics, and each might originate an attack of urticaria. Dr. Russell quoted one remarkable case in his own practice, in which a single enema of laudanum was followed by an outbreak of urticaria of such intensity that he was at one time alarmed for the patient's reason. The patient's daughter suffered from protracted urticaria in two successive pregnancies. In conclusion, Dr. Russell commented on the peculiar contradiction exhibited in his case of contraction of the fibre-cells of the skin, and relaxation of the contractile fibres of the small arteries indicated by the surrounding vascularity; the vascular areola was, however, not a necessary attendant even of the present form of urticaria. His friend, Dr. Denne, mentioned to him a case in which the wheals produced by irritating the skin were free from any areola. He suggested as a subject of some interest to watch the effect of drawing the nail over the healthy skin in different individuals.

7. Dr. MACKEY showed a specimen of Patent Foramen Ovale. A history of the case is published at page 666.

8. Mr. WEST brought forward a specimen of Fracture of the Anatomical Neck of the Scapula which he had removed, together with the upper arm, from a boy aged 17, after amputation at the shoulder-

joint for a machinery accident, which had smashed the humerus and also the radius and ulna. Mr. West remarked on the extreme rarity of the accident, and also mentioned that in this case he ligatured the axillary artery prior to the amputation, with a view of preventing hæmorrhage, as the boy was in a state of great depression from previous loss. The ligature separated on the fourteenth day, and the boy was able to sit up, the greater part of the incision being united.

T. B. CURLING, Esq., F.R.S., President, in the Chair.

A CASE OF UNILATERAL ATROPHY OF THE TONGUE.  
BY WM. FAIRLIE CLARKE, M.A., F.R.C.S.

MRS. H., aged 45, had a malignant tumour removed from her right breast on February 16th, 1870. The wound healed slowly, but satisfactorily. On April 15th she complained of cough and slight dyspnoea, the latter only noticeable after exercise. Under treatment, the cough soon disappeared, but the dyspnoea continued. On October 3rd, Mr. Hume, of Islington, was called suddenly, and found her suffering from a deep-seated pain on the right side of the head, of a periodic character, returning each night between 1 and 2 o'clock A.M., and rendering her for some hours incoherent and unmanageable. The only thing which gave her relief was morphia in grain doses. At this date, atrophy of the tongue was first noticed, though it was not then so marked as it afterwards became. On March 29th, 1871, Mr. Hume was again urgently required to attend, and found the patient suffering from all the old symptoms in an aggravated degree; she had also alarming dysphagia, with paroxysms of suffocation, which recurred about three times in the twenty-four hours. On being asked to protrude the tongue, she always appeared unable to do so at first; and, after a few moments, put it out very slowly. The tongue was puckered and crimped along its whole right side from base to apex, mostly at the anterior two-thirds. An actual loss of substance had taken place, but it was bounded exactly by the median raphe; and the contrast between the plumpness of the left side and the shrivelled aspect of the right was very striking. When it was protruded, there was no deviation to either side. Articulation was slow and difficult. There was great pain along the right side of the neck, with a certain fullness and turgescence of the vessels; but no tumour could be felt in any part of the mouth or neck. Together with these symptoms, there were general cachexia and great prostration. From this time the dysphagia and dyspnoea gradually became worse; and on June 7th, in one of the attacks of suffocative cough, the patient died. At no time during her illness had there been any paralysis of the extremities, and her intellectual faculties remained clear throughout.

Unfortunately no necropsy could be obtained; but, looking at all the circumstances of the case, Mr. CLARKE thought there was good reason to believe that the ninth nerve on the right side was involved in a secondary cancerous tumour, such tumour being situated either within the cranium or at the upper part of the neck, and pressing upon the right hypoglossal nerve, and more or less implicating the pneumogastric and glosso-pharyngeal nerves as well.

The writer then proceeded to compare with this case two other instances of well-marked unilateral atrophy of the tongue: the one related by Dupuytren in the *Leçons Orales* (lecture on Hydatid Tumours); the other by Sir James Paget, in the third volume of the *Transactions of the Clinical Society*. The experience of Romberg and of Bidder was adduced to show that this remarkable condition of the tongue might be produced by a lesion of the ninth nerve; and to establish the same point the author related an experiment that he had made. On October 25th, he divided the right hypoglossal nerve in a rabbit, and took out a piece about a quarter of an inch in length. Immediately after the operation, and during the whole time that the animal was under observation, the tongue was strongly protruded to the right side. On November 27th the rabbit was killed. It was found that the nerve had united by a soft gelatinous and highly vascular substance, of about twice the ordinary calibre of the nerve. The right side of the tongue, along its posterior half, was slightly wasted and flattened.

The preparation was exhibited; and an outline sketch, illustrating the case which had been related, also accompanied the paper.

Dr. JOHN HARLEY agreed that the lesion of the tongue in Mr. Clarke's case was probably due to cancer pressing on the ninth nerve. But lateral deviation of the tongue also took place in some cases of scarlet fever, where the deeply seated glands of the neck were enlarged and pressed on the hypoglossal nerve. He had met with this in a lad

aged 15, who had also occipital pain and vomiting; the tongue deviating to the right when protruded.—Dr. CHARLTON BASTIAN thought it by no means certain that atrophy of the tongue was always produced by paralysis of the hypoglossal nerve. At the Hospital for Paralysis and Epilepsy, he had seen a case where the only nerve that could be found affected was the sixth; the tongue, was much wasted, but the deviation was very slight; and when the wasted half was tested by faradisation, decided contraction took place. Dumesnil had a case of general muscular atrophy with paralysis of the tongue and face on one side; there was complete paralysis of the hypoglossal nerve, but no wasting of the tongue. The anterior roots of many of the spinal nerves were much atrophied; as were also the roots of the facial and hypoglossal nerves, while those of the fifth pair were healthy. Dr. Jaccoud, in referring to this case, explained it by supposing that the sympathetic or trophic nerve-fibres went to the tongue with the branches of the fifth rather than with those of the motor nerves.—Dr. HABERSHON referred to the case of a woman in Guy's Hospital in whom, while she was suffering from cancer of the breast, the right side of the tongue became flaccid and wrinkled, the organ being turned to the right. Speech and the sensation of the organ were unimpaired. The right sternohyoid muscle was paralysed; the posterior belly of the omo-hyoid contracted on each side. The patient had pain at the back of the head, and pain and tenderness down the spine. After death (which took place from wasting), numerous soft cancerous tubera were found implicating the bones of the skull and the dura mater; and one of them crept up from the foramen magnum to the internal auditory meatus, involving the eighth and ninth nerves. The proximity of the disease to the meatus explained a slight affection of the facial nerve which had been noticed during life. The affection of the tongue was evidently due to the interference with its nerves by the medullary cancerous growths.—Dr. HUGHLINGS JACKSON thought Mr. Clarke's case a very rare one. In no instance had he seen palsy of the tongue, either on one side or on both sides, without palsies of other parts. Thus in a case of syphilitic disease there was palsy of the left portio dura and eighth nerves, as well as of the left ninth nerve. In a case of tumour of the medulla oblongata and pons Varolii, there was palsy of the fifth, sixth, seventh, and eighth nerves, as well as of the ninth, on the left side, and paralysis of the right arm and leg. He mentioned a case of a man who found out one morning that he was hoarse, and that his tongue was turned to one side "like a hook." There was palsy, with wasting, of the right side of the tongue, paresis of the right side of the palate, and palsy of the right vocal cord. As the man was past fifty years of age, as he had albuminuria, and as symptoms came on in one night, the probability was that they were the result of clot. In one case of sudden palsy of the tongue, palate, and orbicularis oris which he had seen, Dr. Lockhart Clarke discovered relics of effusion of blood in the medulla. Dr. Lockhart Clarke's researches, showing the close relations of the lingual and spinal accessory nuclei, gave the explanation of cases of lesions in the medulla producing palsies of the several factors concerned in articulation, deglutition, and voice. Dr. Hughlings Jackson had never seen wasting of the tongue from paralysis of the fifth nerve, although the temporal and masseter muscles wasted.—Dr. WILLIAM OGLE referred to a case related by Dr. Hyde Salter in his article on the Tongue in the *Cyclopædia of Anatomy*, in which paralysis and atrophy of the tongue were produced by a wound of the neck injuring the hypoglossal nerve. He had often divided the hypoglossal nerve in animals, and had found that the tongue did not always deviate towards the side of the lesion; sometimes it was protruded straight, sometimes it was even turned a little to the opposite side. This last occurrence was difficult to explain; it might occur in cases of disease of brain, where the lesion was double; or possibly the observation might be made when the tongue was partially withdrawn after protrusion, and when, from a reversal of the muscular action, it would appear somewhat pushed to the other side. Section of the hypoglossal nerve caused the tongue to be as it were turned up, the paralysed side being the higher. He asked if this had been noticed in disease.—Dr. HILTON FAGGE had seen a case of unilateral atrophy of the tongue in a boy aged 5½ years. A piece of the odontoid process was found sticking up through the dura mater.—Mr. THOMAS SMITH thought the action of the genio-hyo-glossus muscle sufficient to draw the tongue over to the paralysed side. This muscle protruded the organ; which, when outside the mouth, was moved by the styloglossus muscle; and this, or the lingualis, might draw the tongue towards the sound side.—Mr. HENRY POWER said that the theory of the existence of trophic nerves was almost entirely based on observations of the effect of injury of the fifth nerve on the eye. He thought, however, that little if anything was known regarding trophic nerves. In Mr. Clarke's case, he thought the lesion was not connected with the fifth nerve, but with the hypoglossal. In the case of the eye, he believed that the increased liability to inflammation after injury of the fifth nerve

arose from the organ being more exposed to injurious influences acting from without.—Mr. SOELBERG WELLS referred to some experiments of Meissner, in which sloughing of the cornea did not occur after experiments on the fifth nerve unless the innermost fibres were divided.—Mr. R. B. CARTER said that, in patients who had died with herpes zoster, Bärensprung and Charcot had found signs of disease in the spinal ganglion. He had seen herpes followed by sloughing of the cornea, without other changes in the eye. Might there not be some change in the Gasserian ganglion?—Mr. BARWELL thought that Mr. Fairlie Clarke's case could scarcely be regarded as one of recurrence of cancer after operation.—Mr. HOLTHOUSE briefly related a case of unilateral atrophy of the tongue in a syphilitic subject.

## INTERMENSTRUAL OR INTERMEDIATE DYSMENORRHOEA.

BY W. O. PRIESTLEY, M.D.

The author pointed out that, although much had been written concerning dysmenorrhœa, and several forms of it had been described in accordance with the pathological views taken of its causes, the description of the several varieties was ordinarily limited to the time of the catamenial period, with the two or three days additional which might precede and follow the menstrual flow. From time to time, however, cases of a more obscure kind presented themselves, in which the chief suffering was remote from the actual menstrual period, but came on, nevertheless, with the same punctuality, and was probably dependent on organic changes associated with the production of the catamenia. Probably other practitioners had observed like instances, as they were not unfrequent, but the author had met with no description of them.

In all the cases detailed severe pain was experienced by the patients midway in the menstrual interval. The pain commonly came on about fourteen days after a catamenial period, and, after lasting a variable number of days, ceased before the supervention of the next expected period. In one case, the pain, beginning midway in the interval, ran into the following monthly period, and was relieved by its flow. The suffering was constantly referred to one or other ovarian region, and, in three cases out of four, marked tumour, or thickening from old adhesions, was found in that locality.

The reason for the occurrence of pain in the intermenstrual period, and with such regularity, was not, in the present condition of our knowledge, perfectly obvious. A study of the physiological and pathological conditions left little doubt, however, that it was due to perturbations in the function of "spontaneous ovulation" habitually going on in the ovary. Hypertrophy of the structure of the ovary, or thickening of its indusium, would lead to undue vascular excitement, and impede the advance of ova to the surface in their attempts to attain maturity. It was not unreasonable to suppose, from all known facts of the case, that preparation for an approaching period began in the ovary ten or fourteen days before the occurrence of the monthly uterine discharge; and if the initial steps in the process of ovulation were opposed by certain pathological conditions, pain would ensue. Nay, in the absence of distinct organic change, it might readily be imagined how special irritability in the ovary would cause an unusual amount of disturbance whenever there was occasion for the exercise of fresh activity in the organ. This latter class of cases would partake more or less of a neuralgic character.

The treatment would depend on the pathological condition as ascertained by examination. The pain being only a symptom, it would be needful to inquire into the cause; and if there were tumour, or thickening depending on former inflammation, absorbent remedies would be indicated. If no organic change of structure could be detected, anti-neuralgic remedies, such as quinine, iron, and arsenic, would best answer the purpose of cure.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 24TH, 1871.

G. OWEN REES, M.D., F.R.S., Vice-President, in the Chair.

*Intracranial Disease cured by Iodide of Potassium.*—A young man, aged 21, was admitted into Guy's Hospital, under Dr. MOXON'S care, having been ill six months. The illness came on with severe headache; in about three months, ptosis and ocular paralysis of the left side commenced, and, as it went on, the left fifth nerve also became involved, and the right hand grew partially numb. When admitted, the patient had agonizing pain in the head. The left eye was intensely red, and its cornea ulcerated; it was almost immovable, and the lid was dropped. He could not feel moderate touches on the left side of the face, nor taste salt on the left side of the tongue, nor use the left masticating muscles. He had two slight seizures of a doubtful kind on the first two days after admission. Iodide of potassium was

given in three-grain doses thrice daily, and the dose increased to a scruple. The pain left him very soon, the other symptoms more gradually. He was in attendance at the Society's rooms, and the state of the left side of his face and of his left eye was practically normal again. This was the third case of syphilitic disease about the sella Turcica Dr. Moxon had met with. This he connected with the growth of the sphenoidal sinuses there, bringing in illustration the occurrence of exostoses very frequently about the frontal sinuses and of exostoses on the long bones at the region of the epiphyseal cartilage; all these facts going to prove that the seats of late development were unusually liable to disease. Dr. Moxon believed that it was incumbent on every one who had a case of local intracranial disease come under his care, to treat it at once with iodide of potassium, without waiting to make out its nature. He had not seen any serious ill effects from the iodide when taken to the extent of a drachm in the day for long periods. Slight salivation, a red rash, and catarrh were not common, though they occasionally occurred; and they were by no means to be compared with local intracranial disease as alternatives. As to absorption of the testes, he had never seen it. The iodism of old authors was probably to be referred to the poisoning of the blood by the absorption into it of broken-down matter of gottres during their cure.

Dr. ANSTIE read the further and concluding history of a case of which the earlier notes were read last session. It was an example of neuralgia of all three branches of the fifth nerve, immediately excited by constitutional syphilitic infection, and which was of recent date. The case was one of a remarkable character. The nerve had been predisposed to neuralgic pain; many years before the syphilitic infection it had been the seat of an ordinary typical *migraine*, of great severity; and at present it was very noteworthy that the painful and tender points were distributed, not according to the type of tertiary syphilis, but according to that of ordinary neuralgia. Moreover, a number of secondary lesions (unilateral facial anaesthesia, unilateral loss of taste in the tongue, unilateral spasm of muscles, etc.) were distributed exactly as such secondary affections were in severe neuralgias where there was no question of syphilis. Besides these curious phenomena, there were a series of paralyses of the ocular muscles, quite of the ordinary syphilitic type. Thirty grains of iodide of potassium daily completely cured the neuralgia, the anaesthesia, the loss of smell and taste, and the muscular spasms, in little more than a fortnight. The ocular paralysis proved exceedingly obstinate; but the prolonged use of iodide in larger daily doses (forty-five and then sixty grains) at last completely removed it. It was a singular fact that, during the full progress of the muscles towards recovery, unmistakable symptoms of iritis made their appearance; they were checked by a short course of mercury. Such a case as this was sure to be marked, in the future, by the repeated recurrence of tertiary syphilitic nerve-lesions.—Dr. HUGHLINGS JACKSON thought there could be no reasonable doubt as to the correctness of the diagnosis of syphilitic disease; since several cranial nerves were paralysed on but one side. Moreover, the palsies had passed off under antisiphilitic treatment. Dr. Moxon's remark, that patients cured of syphilitic affections of the nervous system were liable to suffer again, was of great practical importance. He (Dr. Jackson) thought unfavourably of cases of syphilitic affections of the nervous system, even after the symptoms had been promptly removed by drugs. The author's observation on the indirect way in which nervous centres suffered from syphilis by plugging of syphilitic arteries, was very important. Although patients would recover from hemiplegia the result of any kind of pathological change, provided the lesion were very limited, he did not think that the iodide was of value in removing hemiplegia the result of plugging of a syphilitic vessel, any more than in removing hemiplegia the result of embolism from heart-disease. He asked if the patient had had a blow on the head, as he had frequently seen cases in which syphilitic affections of the nervous system followed severe blows on the head. In illustration, he mentioned the case of a woman whose history he had related two years ago at this Society, who, after a severe blow on the left side of her head, had double optic atrophy (the sequel of neuritis), and convulsions beginning in the right hand. At the necropsy there was found syphilitic disease of the surface of the left hemisphere, and also of the liver and spleen.—Mr. BRUDENELL CARTER was of opinion, from the condition of the optic discs, that the disease was consequent on inflammation, and not on a tumour. He considered it going too far to say that iodide of potassium should be given, as a rule, in local intracranial disease; and believed that in some cases it was better to give mercury. The results obtained from iodide of potassium were, he thought, more satisfactory when the drug was given in fine division, as in a large quantity of barley-water. In patients who were susceptible to small doses, the effects of the drug might be still obtained by diminishing the quantity.—Dr. BROADBENT had seen purpura produced by small doses of iodide of potassium, and had not met with much

catarrh. He always prescribed ammonia with the potassium, and found that the remedy was borne better after a meal. He gave ten-grain doses of the iodide to begin with, as a rule; and had given drachm doses every four hours without effect.—Dr. BUZZARD said that many of the cases of cranial paralysis presented no history of syphilis at all; and it would be interesting to know how far iodide of potassium could remove effusion in such cases. Might there not be, in some of these cases of cranial nerve paralysis, meningitis dependent on other causes—as, for example, rheumatism? Iodide of potassium, he had found, could be used as easily as bromide of potassium.—Dr. ALTHAUS remarked that large doses of iodide of potassium were often borne better than small, and that liquor arsenicalis was a good corrective. He alluded to a case of rheumatic meningitis with hemiplegia, cured by iodide of potassium. He wondered that Dr. Anstie, in his case, had not applied electricity, which has much influence in local paralyses.—Mr. HOLTHOUSE alluded to a case in which petechiae were produced by the use of iodide of potassium. He had always looked upon the cases in which this drug did good as syphilitic; but it was often impossible to get a syphilitic history.—Mr. LAWSON remarked that it was not frequent, as in Dr. Moxon's case, for the eyes to become bloodshot in ptosis. It was generally in the reverse condition that ulceration of the cornea took place.—Dr. ANSTIE, on the other hand, observed that it was not necessary to have the eyelid open to have ulceration; while Mr. BRUDENELL CARTER pointed out that Schiff and others had shown that, if the inner part of the fifth have been paralysed, the cornea becomes ulcerated.

*Uncomplicated Aphasia.*—Dr. GLOVER described a case of aphasia in a patient under his care at the Holloway and North Islington Dispensary. G. P., aged 63, an intelligent workman in a varnish and colour manufactory, came under treatment in the beginning of September with a very imperfect power of expressing himself, a furred tongue, high-coloured urine, and a weak pulse. The affection of the faculty of language was peculiar. Many words the patient could say quite well, but he was greatly embarrassed for want of the proper words. This appeared in his attempt to answer questions, and especially when asked to say what the names of particular objects were. Dr. Glover gave several curious illustrations. One day, on being shown a book and asked what it was, he said, "good," "house," "butter." On being asked to write the name, he said, "a good"; then he remembered the right word, and said "book." On a watch being shown to him, and being asked for the name of it, he said, "*Tempus fugit*," but could not say the proper word; but, on being asked to write it, he wrote "watch." He called a ring "a knife," and purse "bug," "book," "bug," "a pocket-book." One day, after naming the door and the fire, and being asked the name of the window, he was greatly puzzled, and said, "five," "glass and sash;" he was then quite confused for a few minutes, and being asked to write it, he put "fireaway," "fender," "windway," "windway," "shot," "lock." Ten days later, being asked the same question, he said "windle," and quickly "a window." He seemed to know when he answered wrongly, and was sometimes impatient, and sometimes amused at his errors and his embarrassment. There was no other symptom of cerebral disease, no hemiplegia, and either none or but the slightest difference in the sensation of the two sides. He walked well, wrote fairly, shaved well, and protruded his tongue straight. Dr. Glover remarked that the case was especially interesting for being simple and uncomplicated with any lesion of intelligence or of motion, such as right hemiplegia. There was nothing to indicate any affection of the left hemisphere more than one of the right, as M. Broca's remarkable theory supposed, which localised this disease in some lesion of the third left anterior convolution. Seven or eight months ago, the patient had had a similar attack, which only incapacitated him for work one whole day, by reason of the way in which he put wrong names on the varnish cases. The present attack began about eight o'clock one morning in the water-closet. He seemed to lose himself. He foamed at the mouth, and fell down, but not quite unconsciously, for he tried to save himself. He lost his speech, but spoke a little, cried a little, and seemed inclined to fret. He walked home with the help of a young man, who gave these particulars of the attack, and who thought that at the time the face was drawn to the left side. There was no drawing of the mouth since Dr. Glover attended him, and he saw him the day after the attack. Occasionally, the heart and pulse were irregular. At other times, and generally, they were regular, but weak. There was no abnormal sound. Mr. Carter had kindly examined the eyes, but the existence of lenticular opacity made it impossible to get any help in diagnosis from the state of the fundus. The patient's previous health had been good, excepting yellow fever in 1833 or 1834. He never had rheumatism or syphilis. The treatment at first was chiefly expectant. Latterly, ammonia and a little wine and beef have been its principal features. The aphasia had become rather less,

though still persistent. Dr. Glover thought the symptoms might be attributed to either softening, or embolism, or slight extravasation affecting a very limited portion of the brain, and inclined rather to extravasation, from the persistence of the aphasia and the nature of the attack. The patient was present, and was examined by various members of the Society.—Dr. BEÜMLER said that he had several times seen temporary coma produced by lead; but Dr. GLOVER, in answer to Dr. Bäumler, remarked that he had examined the patient and his history carefully, and found no evidence of lead-poisoning.—Dr. HUGHLINGS JACKSON thought that, since the patient made mistakes in words, and could not express himself correctly in writing, the author was justified by usage in calling the very interesting case he had reported one of aphasia; but he suggested that this term should be restricted to cases of more or less loss of speech. He thought that a term was wanted for the other condition, that of disorder of speech—mistakes in words, for instance. He believed that these two conditions were fundamentally opposite conditions, and that the mental states of the patients were different. For example, in cases of loss of speech, the patient readily understood what was said to him; whereas, in cases where making mistakes in words is the chief phenomenon, it frequently happens that the patient did not readily understand what is said to him. He supposed that disorder of speech was more frequently the result of plugging of vessels, in young people especially, than of other pathological lesions, such as clot; but could not speak so confidently on this point as he had formerly done. The absence of hemiplegia in cases of affections of speech was very uncommon. Occasionally the hemiplegia passed off when even complete loss of speech remained; but it was very rare for there to be absolutely no one-sided paralytic symptoms at first.—Dr. BROADBENT said the case was one of amnesia, the patient making mistakes in words; and he would, therefore, not look to the third frontal convolution for the disease.—Dr. ANSTIE said that he had seen a case in which this confusion of the name of one object with another occurred during an attack of autumnal diarrhoea.—Dr. MOXON thought that aphasia meant that state in which words were forgotten, and could not be used when repeated.

#### MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

WEDNESDAY, NOVEMBER 29TH, 1871.

AQUILLA SMITH, M.D., in the Chair.

*Phosphorus in Skin-Diseases.*—Dr. JAMES LITTLE read for Dr. EAMES, who was unavoidably absent, a paper on this subject. It commenced with a brief review of the observations of Burgess, Broadbent, and Tilbury Fox on the employment of phosphorus as a substitute for arsenic in the treatment of many cases. Dr. Eames described his method of using the remedy. A solution of ten grains of phosphorus in one ounce of olive oil was prepared, and of this a dose of from five to ten minims was administered three times a day; or capsules might be substituted in cases where the oily solution caused nausea or other unpleasant symptoms. Three sets of capsules, containing one-tenth, one-twentieth, and one-thirtieth of a grain of phosphorus respectively, had been made. The first case treated by Dr. Eames with the remedy was one of severe *acne indurata* of the face, of four years' standing. After six weeks, a cure was effected. In three cases of lupus, similar satisfactory results were obtained. In the first of these, a marked improvement was observed after a fortnight's trial, and the patient continued to take ten-minim doses of the phosphoretted oil for nine months. In the second instance, a five months' course of treatment was followed by cicatrization, and, eighteen months subsequently, there had been no return of the disease. In the third case, the oil was used during nine weeks, but with interruptions, owing to the appearance of grave dyspeptic symptoms. In one case of scrofuloderma, the glandular swellings disappeared in six weeks; in another, a cure was effected in three weeks. Psoriasis also yielded readily. In one instance of this affection, dyspepsia supervened on the administration of phosphorus, which was then temporarily stopped and the mineral acids given. A man, aged 24, with pemphigus, beginning on the abdomen, was quite well in a month. Cases of eczema of the scalp had also been much relieved. Dr. Eames referred to the silvery appearance of the tongue noticed when patients had been taking phosphorus for some time—another point of analogy with arsenic, and to the frequent occurrence of dyspepsia. The latter was to be met by substitution of the mineral acids for a short time.—Dr. QUINLAN had used phosphorus with great advantage in various cases where depression was a marked symptom, especially in pneumonia. He had occasionally used the amorphous or red phos-

phorus. The combination of dilute phosphoric acid and cinchona was a most useful tonic.—Dr. H. KENNEDY believed Dr. Eames's paper to be a very valuable contribution. He spoke of two remedies which he had used with success in lupus; namely, the insertion of an issue, and the internal use of elm-bark.—Dr. JENCKEN had made experiments with an alcoholic preparation, which had answered very well.—Dr. GRIMSHAW objected to any comparison being made between dilute phosphoric acid and phosphorus, as the former had nothing in common with the latter. He congratulated Dr. Eames on the clearness of his communication, and for having so thoroughly isolated the treatment by phosphorus in all his cases.—The CHAIRMAN alluded to the largeness of the dose used by Dr. Eames with advantage. He objected to the substitution of the allotropic variety of the metal.

*Elephantiasis Græcorum.*—Dr. HAWTREY BENSON read an account of an interesting case of elephantiasis Græcorum. The patient, who was in attendance, was a man, 47 years of age, a native of the County Kilkenny. He had served in India for twenty-seven years, but returned to Ireland in 1869. Nine months ago, his health began to fail, and slightly febrile symptoms appeared. He complained of sensations of creeping, itching, and tingling in the backs of the hands, subsequently extending to the face, neck, and shoulders. On coming under the care of Dr. Stearne, of Thomastown, that gentleman found the patient's body to be in places of a dusky, almost coppery hue. In other parts, too, the skin was indurated. Again, in certain situations, elevations were discovered. When he was sent to Dublin, the mouth had become engaged, and, under the tongue, several tubercles had ulcerated. The urine was healthy. No anæsthesia existed. He was treated with arsenic, warm baths, etc.—The CHAIRMAN asked whether there was any history of contagion in the case.—Dr. H. STEWART inquired as to the patient's temperance or otherwise.—Dr. H. KENNEDY asked whether it was satisfactorily established that the leprosy of the Bible was identical with elephantiasis Græcorum.—Dr. JAMES LITTLE thought that the local disease was quite distinct from that brought before the meeting by Dr. Benson. He had seen the affection in Egypt. The loss of the phalanges of the hands and feet was a notable feature in aggravated cases. Laryngeal complications were also common, so that the "leper's cry" was well known to the people of those countries where the disease was endemic.—Dr. ARCHIBALD JACOB suggested that exposure of the parts of the body affected to light or air influenced the degree of development of the disease.—After some remarks from Drs. CROLY and WHARTON, Dr. BENSON replied. He had not been able to obtain any evidence of contagion, but the patient had been rather intemperate. The disease was generally believed to be identical with the Biblical "leprosy", though the latter was the anæsthetic form of the affection, in which large white patches of skin were a distinctive feature. In the same form occurred the loss of the phalanges mentioned by Dr. Little—this being a neuro-paralytic symptom.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, DECEMBER 2ND, 1871.

JAMES STANNUS HUGHES, M.D., President, in the Chair.

*Aneurism of the Arch of the Aorta.*—Dr. MACSWINEY exhibited an aneurismal tumour involving the ascending portion of the arch of the aorta in a woman aged 40. The symptoms first showed themselves two years ago, the most prominent being pain in the chest, occasional palpitation with difficulty of breathing, and cough of a ringing harsh character. The pain complained of was of two kinds. There was a dull, gnawing, constant pain; and to this, at times, was added a sharp paroxysmal one, which ran down the right arm even to the fingers. When admitted to hospital, the patient's face was cedematous, of a livid hue; the veins on the right side of the face and neck were turgid and enlarged. The radial pulse of the right forearm was rather more feeble than that of the left, and its systole was not synchronous with the beat of the latter. On examining the chest, a slight prominence was noticed over the second rib on the right side. This engaged the two neighbouring intercostal spaces also. In the same situation, a secondary centre of pulsation existed, and a double sound was heard on auscultation. Râles were universally audible over the right lung. The patient died early in October last, after a severe paroxysm of orthopnoea. At the necropsy, the right pleura was found to be extensively adherent, the anterior portions of both lungs were emphysematous, and numerous adhesions existed in the pericardium. The heart was in general healthy, but the orifice of the superior vena cava was almost entirely occluded. An aneurism, bilobed, engaged the whole ascending aorta from its origin, and extended to the springing of the left subclavian. The larger

of the lobes was five inches in length by four inches in width. The superior vena cava, both innominate veins, the right subclavian and internal jugular veins, were completely obliterated, while the right external jugular was much dilated. No rupture of the sac had taken place, the cause of death having been apparently orthopnoea, the result of bronchitis.

**Large Aneurism of the Left Subclavian.**—Mr. TUFNELL presented a cast illustrative of the external changes induced by the increasing dilatation of a remarkable aneurismal tumour, or series of tumours, a drawing of the same, and the bony structures of the left half of the thorax, showing the ravages caused by the pressure on them of the sac. The patient was a soldier in the 46th Regiment, a comparatively young man, and had been for the first six months of his illness under the care of Mr. Longmore at Netley. He had suffered from venereal disease. In March of the present year, pain and stiffness set in in the left shoulder. The hand shortly became numb. He soon noticed a swelling above the collar-bone. When he first came under observation, the left pupil was dilated. A very marked clubbing of the nails on the left hand became developed in the course of some time. Two large tumours, separated by the clavicle, existed on the left side. Regarded as one, these were somewhat pyriform in shape. They were readily emptied by pressure, at least to a large extent, and a blowing sound was extensively audible over them. On raising the arm above the shoulder, they also were largely emptied. In September, the man came under Mr. Tufnell's care. The shoulder was now pushed up to a level with the ear. The poor man suffered terrible pain, which was alone relieved by hypodermic injection of morphia. His daily dose of the alkaloid at last rose to six grains. He died of exhaustion. The skin over the swelling was of a dirty yellow hue, in places very dark. The left clavicle was eroded on its under surface. Three aneurisms of the subclavian were found. Of these, one sprang from the first stage of the vessel, being of the size of a hen's egg; the other two arose from the second stage, one forming the supraclavicular tumour, the other passing downwards, and becoming an axillary aneurism. It was the last that had produced the greatest pathological changes. In consequence of its pressure, the left lung had become completely cancrified. The first rib had totally disappeared, the second was more than half absorbed, and the third, fourth, and fifth ribs were thoroughly dissected out. The heart and right lung were quite healthy.

**Polypoid Growth of Left Auricle.**—Dr. ROBERT M'DONNELL regretted that no history of the specimen which he presented was forthcoming. A polypus as large as a plum, having a pedicle and serous membrane, had grown from the edge of the fossa ovalis into the left auricle of the heart. The tumour dangled close to the auriculo-ventricular opening, probably into the appendix. The growth might originally have been a fibrinous clot, which became organised, or it might have resulted from some inflammatory process, slight traces of which were found elsewhere in the left cardiac chambers.

**Rapid Formation of Cancerous Deposits in a Young Man.**—Dr. STOKES laid before the Society the thoracic and abdominal viscera of a man, aged 22 or 23, in many of which large depositions of cancerous material had taken place within less than two months. The man had been very intemperate. Ten weeks ago he got a wetting. In about a fortnight, the legs swelled. He soon came into hospital. He was generally anasarcaous, had shortness of breathing, bronchial râles, and a feeble pulse. There was slight ascites, which did not afterwards increase; a circumstance to which Dr. Stokes drew particular attention, as being characteristic of this symptom when observed in cancerous affections. About twenty nodules were noticed over the surface of the abdomen, most of them of the size of hazel-nuts. A large tumour also projected above the clavicle. Profuse watery diarrhoea occurred. On one occasion twenty-eight stools in one night were passed, and the patient quickly sank. The swellings were all between colloid and true canceroid in character. The heart, which was small and atrophied, presented many nodules. The pleurae were affected, and also the mesenteric and other abdominal glands. Of these, some had a melanotic hue. The liver had quite escaped. Not long before his death, the man had suffered excruciating pain in the epigastrium, and here was found a large, evidently recently formed, mass of cancer.

**Molluscum Scaberrimum.**—Dr. W. G. SMITH exhibited a portrait of this affection taken from life from a patient lately under his care in the Adelaide Hospital. The neck, chest, arms, and abdomen were thickly studded with the characteristic growths. The largest was situated over the left rectus abdominis muscle, and its dimensions were 3 by 3½ inches. They were mostly sessile, on a broad base. The parts most usually affected, the face and genitals, were in this instance free from any tumours.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board, on December 6th.

Bodman, Francis Henry, Devizes, Wilts: diploma of membership dated July 28th, 1871.

Harbinson, Alexander, Newry, co. Down: November 17th, 1871.

Hughes, Evan Thomas, Tanyralt, Llanfachraith, Anglesea: July 25th, 1871.

Two other candidates having failed to acquit themselves to the satisfaction of the Board, were referred. At the ensuing preliminary examinations in Arts, etc., for the Diplomas of Fellowship and Membership of the College, commencing on the 19th instant, 72 candidates have entered their names for the first named distinction, and 232 for the latter, making a total of 304 against 337 last December. The examinations will be conducted as heretofore at the Whittington Club, by a staff from the College of Preceptors, under the superintendence of the Rev. Dr. Jacob.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 30th, 1871.

Dickson, Thomas, Preston, Lancashire

Oates, James Pimlott, Stourbridge

The following gentlemen also on the same day passed their first professional examination.

Bevers, Edmund Augustine, Guy's Hospital

Comfield, Thomas, London Hospital

Manser, Robert, Guy's Hospital

Vowell, Charles Martin, King's College

As Assistants in compounding and dispensing medicines.

Pattinson, Dan, Dearham, Cumberland

Simpson, John, Colchester

Williamson, Nicholas, Harrington, Cumberland

## MEDICAL VACANCIES.

The following vacancies are announced:—

ABERDEEN DISPENSARY—Medical Officer.

AMERSHAM UNION—Medical Officer and Public Vaccinator for the Chesham

No. 2 District: £70 per annum, and extra fees.

BLYTHING UNION, Suffolk—Medical Officer for District No. 1. Medical Officer

and Public Vaccinator for the Wrentham District: £43 per ann., and extra fees.

BRADFORD FEVER HOSPITAL—Resident Medical Superintendent: £120 per

annum, and board, first year.

BRIGHTON AND HOVE DISPENSARY—Two Surgeons.

CARNARVONSHIRE AND ANGLESEY INFIRMARY and DISPENSARY,

Bangor—House-Surgeon: £80 per annum, board and lodging.

DENTAL HOSPITAL OF LONDON—Lecturer on Dental Surgery and Patho-

logy.

DEVON and EXETER HOSPITAL—Surgeon.

EARLSWOOD ASYLUM FOR IDIOTS—Assistant Medical Officer: £150 per

annum, board and apartments.

EAST RETFORD UNION, Nottingham—Medical Officer for the Dunham District.

GOREY UNION, co. Wexford—Medical Officer to the Workhouse and Infirmary.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street—House-Surgeon.

JERSEY GENERAL DISPENSARY—Resident Visiting and Dispensing Medi-

cal Officer: £100 per annum, furnished rooms, attendance, coal, and gas.

KILBURN, MAIDA HILL, AND ST. JOHN'S WOOD GENERAL DIS-

PENSARY—Resident Medical Officer: £100 per annum, furnished rooms, £45

per annum for a dispenser and servant, coal and gas.

LIVERPOOL—Public Analyst for.

LIVERPOOL SOUTHERN HOSPITAL—Senior House-Surgeon: £105 per

annum, board and lodging.

METROPOLITAN FREE HOSPITAL, Devonshire Square—Hon. Surgeon.

NORTH MAVERNE and DELTING, Shetland—Parochial Medical Officer.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill—House-Physician: £80

per annum, board, furnished apartments, and washing.

NUNEATON UNION—Medical Officer and Public Vaccinator for the Nuneaton

District: £55 per annum, and extra fees.

ROYAL INFIRMARY, Manchester—Senior House-Surgeon.

ST. PANCRAS, Middlesex—Medical Officer for the Workhouse and Infirmary.

ST. PANCRAS and NORTHERN DISPENSARY—Resident Medical Officer.

SEAMEN'S HOSPITAL (late Dreadnought), Greenwich—House-Physician.

STOCKWELL FEVER HOSPITAL—Resident Medical Superintendent.

TORQUAY, Devon—Medical Officer of Health: £100 per annum.

TOXTETH PARK TOWNSHIP—Medical Officer for District No. 2: £250

per annum.

UNIVERSITY COLLEGE HOSPITAL—Assistant Obstetric Physician.

WEST BROMWICH DISTRICT HOSPITAL—House-Surgeon: £70 per annum,

board and residence.

WEST OF ENGLAND EYE INFIRMARY, Exeter—Surgeon.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*GILLARD, Richard, Esq., appointed Medical Officer to the Hayle's Charity for the District of St. Mark's, Kennington.

\*GLEN, T. R., M.B., late Physician to the Northern Hospital, elected Physician to the Royal Infirmary, Liverpool.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY** .....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**TUESDAY**.—Royal Medical and Chirurgical Society. 8 P.M.: Ballot. 8.30 P.M.: Dr. John Harley, "On the Pathology of Scarlatina; and its Relations to Enteric Fever."

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**FOR** replies to questions concerning Poor-law medical questions, see Poor-law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Maunsell, Dublin.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**DR. W. HENDERSON** (London).—Many thanks.

**OBSTETRICIAN**.—You will find in another column that the examination for the "L.M." of the College of Surgeons took place on Wednesday last. The next examination for it will be about the beginning of February. A certificate of having attended twenty cases will be necessary.

## SPRING STEMS.

**SIR**.—I have had so many applications for the name of the maker of my new stems, that I shall consider it a favour if you will let me state in the next number of the BRITISH MEDICAL JOURNAL, that Messrs. Maw, Son, and Thompson, 10, 11, 12, Aldersgate Street, E.C., and Messrs. Krohne and Sesemann, 8, Duke Street, Manchester Square, supply them in three different sizes; viz. No. 1, two inches in length; No. 2, two inches and a half; and No. 3, three inches.

I am, etc., PERCY BOULTON.

**DR. B. W. FOSTER** (Birmingham).—With much pleasure.

**MR. E. C. BOARD** (Bristol).—Arrived too late.

**ERRATUM**.—In the abstract of Dr. Druitt's paper on Medical Officers of Health, in the JOURNAL of December 2nd, page 653, col. ii, line 27 from bottom, for "denied" that their status and emoluments", etc., read "desired that their status", etc.

**A YOUNG MEMBER** (Plymouth).—You will find the questions of the past year in the Calendar of the College of Surgeons.

**MR. DAYMAN** (Southampton).—Next week.

## STOPPING TEETH.

**SIR**.—I am frequently asked to stop a decayed tooth; and I have recently found that dentists use some kind of amalgam evidently far cheaper than gold and quite as effectual. Can you kindly inform me what the amalgam is, and where it can be procured; or name a treatise on the subject in which I can find the information desired? I am, etc., MAURICE G. EVANS, M.D.

Narberth, December 5th, 1871.

**CHARON'S PENNY**.—It was one of the customs of the ancients to place a coin, or coins, with the corpse on burial, sometimes on the eyes; and an illustration of this may be seen in the Ethnological Collection in the Museum of the College of Surgeons. A satirical writer once said of a well known and notorious empiric the following:

"This quack to Charon would his penny pay,  
The grateful ferryman was heard to say,  
Return, my friend, and live for ages more,  
Or I must haul my useless boat ashore."

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

## ROYAL COLLEGE OF SURGEONS.

The following questions were submitted to the candidates at the last primary examination for the Diploma of Fellow:—1. Describe, in the order in which they occur, the Anastomoses of the Arteries on the walls of the Alimentary Canal, from the cardiac orifice of the Stomach to the Anus.—2. Describe the White Corpuscles of the Blood; and state the evidence which exists concerning their origin and destination.—3. Give the origin, course, relations, and distribution of the Glossopharyngeal Nerve; and describe the dissection required to expose it in its course below the base of the skull.—4. Describe the Cochlea:—a. Its osseous structure; b. Its membranous portion and the structures connected with it; including the mode of distribution of the cochlear division of the Auditory Nerve.—N.B. All four questions must be answered.

At the pass examination for the Diploma of Fellow, on November 22nd, the following questions were submitted:—1. Describe precisely the different modes of performing Amputation of the Thigh; and include amputation at the Knee-joint. State the advantages of each mode of operation and the reasons for selecting it.—2. A Knee-joint becomes acutely inflamed, and the result is a complete ossific union of the bones. Explain the process by which this is accomplished; point out the symptoms pathognomonic of the structural change. State the duties of the surgeon in the treatment of such a case; and the time probably required for its natural course.—3. Give the signs which indicate the impaction of a Foreign Body in the Oesophagus, indicating the points at which it is most likely to be arrested. Mention the various instruments that may be useful for its removal, and the circumstances under which Oesophagotomy may be necessary. Then describe that operation, and give the surgical anatomy of the parts concerned.—4. Describe wounds of the Abdomen—contused, punctured, and incised; mention the parts most liable to be injured; the chief dangers attending these wounds; and give the treatment, general and local, according to the seat, nature, and extent of the wound.—N.B. All four questions must be answered.

**MIDWIVES**.—In my random readings, I came across the following:—Some of the old pew arrangements in Richmond (Surrey) Church, made by the wardens, are curious enough. Two women were particularly located "in regard of their occupations being midwives; and that Mr. Pyke and Mr. Piggot be seated in the gallery with Mrs. Wood." We doubt whether Piggot, Pyke, and the widow, were always so attentive to the discourse as they might have been.

**WE** are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Warminster Herald, Nov. 25th and Dec. 2nd; The Tewkesbury Register, Dec. 2nd; The Liverpool Weekly Albion, Dec. 2nd; The Newcastle Daily Chronicle, Nov. 28th; The Glasgow Herald, Nov. 30th; The Liverpool Daily Courier, Nov. 30th; The Edinburgh Daily Review, Dec. 1st; The Aberdeen Herald, Nov. 25th; The Dudley Herald, Dec. 2nd; The Birmingham Daily Gazette, Dec. 5th; The Scotsman, Dec. 5th; The Norfolk Chronicle, Dec. 2nd; The Aberdeen Free Press; etc.

## COMMUNICATIONS, LETTERS, &amp;c., have been received from:—

Sir Henry Thompson, London; Mr. C. F. Maunder, London; Mr. Bellamy, London; Mr. Fairlie Clarke, London; Mr. William Stokes, Dublin; Dr. George Johnson, London; Dr. C. Barham, Truro; Mr. T. Annandale, London; Mr. F. Mason, London; Mr. Prescott Hewett, London; Dr. Reginald Southey, London; Dr. T. L. Brunt, London; Dr. J. G. Swayne, Clifton, Bristol; Dr. William Newman, Stamford; Mr. Campbell De Morgan, London; Dr. Tilt, London; Our Dublin Correspondent; Mr. Berkeley Hill, London; M.R.C.S.; Mr. Benson Baker, London; Dr. S. Martyn, Clifton, Bristol; Mr. T. Priggin Teale, Leeds; Sir Henry Cooper, Hull; Dr. G. H. Philipson, Newcastle-upon-Tyne; Dr. Edward Waters, Chester; Mr. T. H. Bartlett, Birmingham; Mr. Edward Cock, London; Dr. A. T. H. Waters, Liverpool; Dr. Alexander Fleming, Birmingham; The Secretary of the Hospital for Sick Children; Dr. W. W. Corfield, London; Mr. J. E. Adams, London; Dr. A. W. Edis, London; Dr. F. T. Roberts, London; Mr. J. Croft, London; Dr. Henry Simpson, Manchester; Mr. T. Holmes, London; Dr. R. Greenhalgh, London; Dr. W. H. Broadbent, London; Dr. Hermann Weber, London; Dr. T. Barnes, Carlisle; Mr. W. Hey, Leeds; Dr. E. Symes Thompson, London; Dr. S. O. Habershon, London; Mr. W. W. Wagstaffe, London; Dr. E. Long Fox, Clifton; Dr. Henry Goode, Derby; Mr. Spencer Smith, London; Dr. Chadwick, Leeds; Mr. G. Southam, Manchester; The Secretary of the Royal Medical and Chirurgical Society; Dr. Macleod, Glasgow; Dr. J. Hughes Bennett, Edinburgh; M.D.; Inspector-General Murray, London; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Dr. Lionel Beale, London; Mr. Thomas Cooke, London; Dr. John Harley, London; Mr. Sydney Jones, London; Mr. Holmes Coote, Margate; Mr. W. S. Savory, London; Dr. Leonard W. Sedgwick, London; Dr. George W. Balfour, Edinburgh; Dr. Humphry, Cambridge; Dr. Dyce Duckworth, London; Dr. F. J. Brown, Rochester; Mr. C. Woodcock, Bradford; Dr. Rumsey, Cheltenham; Mr. T. Johnson, London; Dr. Marshall, Clifton; Our Berlin Correspondent; Mr. Joseph Bell, Edinburgh; Dr. Shettle, Reading; An Associate; Dr. Mackey, Birmingham; Dr. J. F. Wilkin, Folkestone; Dr. Braxton Hicks, London; Dr. Hassall, Ventnor; Mr. S. Wood, Shrewsbury; Mr. William Square, Plymouth; Mr. Soelberg Wells, London; Dr. Morell Mackenzie, London; Mr. Board, Bristol; Dr. B. W. Foster, Birmingham; Dr. H. Charlton Bastian, London; Dr. J. W. F. Smith, Aberdeen; Mr. Callender, London; Mr. W. G. Laidlaw, Tranmere; Dr. Elliston, Ipswich; Dr. P. Boulton, London; A Member; Mr. R. Rae, London; Mr. R. Gillard, Clapham Road; Mr. St. George Mivart, London; Dr. Lanchester, Croydon; X. Y. Z.; Mr. Fredk. Waterhouse, Bolton; Dr. McCall Anderson, Glasgow; Dr. Harvey, Aberdeen; Mr. A. T. Norton, London; Mr. Dale, Scarborough; Dr. Templeton, Aberdeen; Mr. Henry Arnott, London; Dr. W. Henderson, London; The Dowager Duchess of Beaufort; The Earl of Carnarvon; The Earl of Lonsborough; Surgeon Major Wyatt; Dr. Sieveking, London; Mr. D. Davies, Bristol; Mr. Hodgson, Brighton; Dr. H. Barnes, Carlisle; Mr. Longmore, Netley; Mr. Jonathan Hutchinson, London; Dr. M. G. Evans, Narberth; Mr. A. H. Carter, Pewsey; Mr. C. Greenhead, Watford; Dr. Vintras, London; Mr. James Lewis, London; Our Liverpool Correspondent; Mr. Le Gros Clark, London; Dr. Handfield Jones, London; Mr. Barrett, Grimston; Dr. Taylor, Scarborough; Mr. Dayman, Southampton; etc.

## THE BUNION SPRING

Is the only effectual remedy for the relief  
and cure of Bunions.

See the Report in the BRITISH MEDICAL  
JOURNAL of Oct. 14, 1871.

TO BE OBTAINED ONLY OF

**W. MILLER,**

ANATOMICAL MECHANICIAN,

29, Leicester Square, London, W.C.

*In ordering, please say which foot.*

## DUNN & HEWETT'S SOLUBLE COCOAS AND CHOCOLATES.

CARACATINA: A Cocoa deprived  
of its butter ... For 1s. and 2s. per packet.  
LICHEN ISLANDICUS, or IOE-Invalids 1s. 4d. per lb.  
LAND MOSS COCOA ...

COCOA & MILK (registered). Prepared with Newnham's Condensed Milk.

To be had of all respectable Grocers and Chemists.

Daniel Dunn was the Inventor & first Manufacturer of SOLUBLE COCOA and  
CHOCOLATE.

Manufactory—Pentonville, London.

TRADE MARK.

PRIZE MEDAL AWARDED, 1862.

### Ladies' Belts.

—The increasing demand for these supports has caused W. H. BAILEY to devote particular care to their manufacture. They are made of various qualities and prices, to suit all who are suffering from the complaints incidental to females.

PROLAPSUS UTERI.

W. H. B. has effected great improvement in the construction of Appliances for the relief of those suffering from this complaint. They are easily adjusted, and may be sent by

MEASUREMENT  
Circumference at A B C. post.

ELASTIC STOCKINGS, etc., for VARICOSE VEINS.

UNIFORMS for day and night.

A Female in attendance.

W. H. BAILEY & SON, 418, Oxford Street, London.

## ROUND SHOULDERS.

Illustrated Pamphlet  
forwarded.

Prices from  
10s. 6d.

## STOOPING HABITS & DEFORMITIES

CHANDLER'S  
CHEST EXPANDING BRACE,

For both Sexes of all Ages.

66, Berners Street, Oxford Street, W.

## SAVORY AND MOORE'S PANCREATIC EMULSION.

Readily miscible in Milk, Water, and Wine.

NOT DETERIORATED BY KEEPING.

### PANCREATINE,

IN POWDER, WINE, AND COCOA.

See "Experiments with Pancreatic Juice."—*The Lancet*, October 16, 1869.

## IMPROVED LIEBIG'S FOOD.

"RESEMBLING MOTHERS' MILK as closely as possible."—Dr. T. H. BARKER.

No Boiling or Straining. Tins, 1s., 2s., 5s., and 10s.

## PEPSINA PORCI PUR.

Free from Starch. Requires no Lactic or Hydrochloric Acid to ensure its digestive activity.

Has more than EIGHT TIMES the digestive activity of the best specimens of the so-called Medicinal Pepsine, or Nutrimental Powder.

143, NEW BOND STREET,  
And all Chemists.

## Van Houten's Cocoa.

The only guaranteed Pure Soluble Cocoa, better and cheaper than any other Cocoa, Cocoa Extract, or any Chocolate.

*The British Medical Journal*, March 27th, 1869, says:—"Van Houten's Extract is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich alkaloid," &c., &c. See also *The Lancet*, etc.

Sold in round Tins at 3s. 6d., 2s., and 1s. Sample Tins, sufficient for a family, free of charge, through your Grocer or Chemist.

Sole Consignee, H. ESCHWEGE, 6 & 7, Coleman Street, London, E.C.

Amsterdam Exhibition, 1869.—The Grand  
Diploma of Honour:

Being the First Prize, and Superior to the Gold Medal.

## Liebig Company's Extract of

MEAT.—Paris Exhibition, 1867—Two Gold Medals; Havre Exhibition, 1868—The Gold Medal. Only sort warranted perfect and genuine by BARON LIEBIG, the Inventor.—"A success and a boon."—*Medical Press and Circular*. One pint of delicious beef tea for 2½d., which costs 1s., if made from fresh meat. Cheapest and finest flavoured "stock" for soups, etc.

CAUTION.—Require BARON LIEBIG's signature upon every jar. Sold by all Italian Warehousemen, Grocers, Chemists, and Ship's Store Dealers.

All Wholesale Houses. And of LIEBIG'S EXTRACT OF MEAT COMPANY (Limited), 43, Mark Lane E.C.

NOTICE.—Various chemical analyses have been published purporting to show a fraction more of moisture to exist in the Company's Extract than in some imitation sorts. It is extremely easy to evaporate the water almost to any extent; but it is quite as certain that the fine meaty-flavour which distinguishes the Company's Extract from all others would be destroyed, if the concentration of the Extract were carried beyond a certain degree. Beef-tea, made from LIEBIG COMPANY'S EXTRACT with boiling hot water, will be found to be greatly superior in flavour, strength, and clearness, to any other sorts. This explains the universal preference it obtains in the market.

This Extract is supplied to the British, French, Prussian, Russian, and other Governments.

## SYR. QUINÆ FERRIQUE SUPERPHOSPH.

ET STRYCHNINÆ PHOSPH.

Is best preserved without change at  
60° Fahrenheit.

Each fluid drachm contains one grain of Quinine, two grains of Iron, and the 32nd part of a grain of Strychnine.

*Curtis & Co.,*

MANUFACTURERS OF PHARMACEUTICAL PREPARATIONS,

48, BAKER STREET, LONDON, W.

Caution.—The Original Makers.

PLEASE NOTICE—SUPERIOR QUALITY—SAMPLES FREE.

## The North London Glass

BOTTLE COMPANY (I. ISAACS AND CO.)—WORKS, LONDON AND YORKSHIRE; Warehouses, 25 and 24, Francis Street, Tottenham Court Road, London, W.C.

List of Prices for NEW MEDICAL GLASS BOTTLES and PHIALS of superior manufacture:—

6 & 8 oz., any shape, plain or graduated	clear	blue	8s. 6d. per grs.
3 & 4 oz. do. do. do.	tinted	8s. od. do.	
1/2 oz. white moulded phials, do.	of a very superior quality	4s. 6d. do.	
1 oz. do. do. do.		5s. 6d. do.	
14 oz. do. do. do.		6s. od. do.	
2 oz. do. do. do.		7s. od. do.	

Prompt attention to country orders. Terms, cash on receipt of goods, and no charge for package. Goods delivered free within seven miles. P.O.O. to be made payable to I. ISAACS AND CO., at the Post-office, Tottenham Court Road, London. Bankers, London & Westminster Bank. Established nearly a hundred years.

## KINAHAN'S LL. WHISKY.

This celebrated and most delicious old mellow spirit is the very CREAM OF IRISH WHISKIES, in quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy.

Note the words "Kinahan's LL. Whisky", on Seal, Label, and Cork.

Wholesale Depôt, 6A, Great Titchfield Street, Oxford Street, W.

## LECTURES

ON THE

## EXPERIMENTAL INVESTIGATION OF THE ACTION OF MEDICINES.

BY T. LAUDER BRUNTON, M.D., D.Sc.,

Joint Lecturer on Materia Medica, and Casualty Physician, at St. Bartholomew's Hospital; etc.

## IV.—DETERMINATION OF THE EXACT STRUCTURES THROUGH WHICH DRUGS AFFECT THE HEART AND VESSELS.

*Comparison of the Effects of Drugs on different Animals in different Doses.—Mode of determining the Exact Cause of Symptoms.—Mode of raising Blood-pressure.—Modes of counting the Beats of the Heart.—Causes of Quickened Pulse.—Direct Stimulation of the Sympathetic.—Stimulation of Cardiac Ganglia.—Paralysis of the Vagus-roots and Fibres, and of its ends in the Heart.—Causes of Slow Pulse.—Irritation of Vagus-roots.—Mode of supplying the Head and Body with different kinds of Blood.—Indirect Irritation of Vagus-roots through the Blood-pressure: mode of lowering and raising it.—Reflex Irritation of Vagus-roots.—Indirect Irritation through the Respiration.—Irritation of Vagus-fibres.—Increased Conducting Power of Fibres.—Stimulation of Vagus-ends.—Paralysis of the Sympathetic.—Paralysis of the Cardiac Ganglia.—Part of the Ganglionic Apparatus Affected.—Nervous System in the Heart.—Motor Ganglia.—Stimulating Ganglia.—Inhibitory Ganglia.—Connecting Apparatus.—Action of Drugs on the Inhibitory Apparatus.—Nicotia, Muscaria.—Antagonism of Atropia and Physostigma: bearing of this on Therapeutics.—Paralysis of Co-ordinating Apparatus.—Paralysis of the Muscular Fibres of the Heart.—Blood-pressure: mode of determining whether changes in it are due to alterations in the Heart or Vessels.—Elimination of the Action of the Heart: Division of its Nerves.—Irritation of Vagus.—Ligature of Aorta.—Artificial Circulation; in Mammals, in the Frog.—Observation of Vessels.—Action on Vaso-motor Centre; on Vascular Walls.—Influence of the Action of Parts surrounding the Vessels upon them.—Action of the Pulmonary Circulation on the Blood-pressure.—Use of the Sphygmograph.*

IS THE SYMPATHETIC PARALYSED?—This is tested by cutting the vagi and dividing the spinal cord between the first and second cervical vertebrae, so as to exclude the action of those centres in the head which quicken the heart and raise the blood-pressure; the drug is then injected, and the sympathetic irritated by an induced current and the pulse counted. If it be quickened by the irritation, the sympathetic is not paralysed.

ARE THE CARDIAC GANGLIA PARALYSED?—To see whether or not the nervous structures contained in the heart itself are acted on by a drug, we must separate it from all other nerves passing to it from without, and prevent its being acted on by anything other than the drug, such as altered blood-pressure or temperature. This is done in mammals by dividing the vagi, the sympathetic cord, the depressor, and the spinal cord between the first and second cervical vertebrae. The heart is thus separated from the quickening and retarding centres, so that any alteration in its beats must be due to the nerves contained in its walls, or the muscular fibre of these walls themselves; at the same time the vessels are separated from the vaso-motor centre, and the heart is thus protected from the effects of any change in the blood-pressure, except the generally unimportant ones produced by the action of the drug on the vascular walls. The number and amplitude of the heart's contractions are then registered by a needle placed in the ventricle, and the blood-pressure by the manometer; poison is injected into the jugular, and the tracings taken afterwards are compared with those taken before. If we find that the heart-beats have become slower and weaker, while the pressure they have to overcome has not been increased, we may conclude that the motor nerves or the muscular substance of the heart have become paralysed. If the blood-pressure have risen, blood should be allowed to flow from an artery till it falls to its previous level, and then tracings should be taken with the needle for comparison with the previous ones.

The action of drugs on the heart can be studied still better in the frog than in mammals, as the heart of the former can be completely separated from the body, so that the drug can be applied to it alone. After its removal it continues to pulsate just as before, and, consequently, any action of the drug on the rhythm or force of its beats can be very easily noticed. The usual way of making experiments on this subject formerly was to take out the heart and lay it in a solution of the poison, or, what was better, to take two glasses containing solution of

chloride of sodium (half per cent.) and add a little of the drug to one of them. A frog's heart was then laid in each, and the beats of the poisoned compared with those of the unpoisoned one. Both of these plans are inferior to that of Ludwig, who supplies the heart with serum so as to keep it as nearly as possible in a normal condition, and attaches to it a manometer, so that it may itself register the number and form of its beats, and give more exact indications than could be obtained by merely looking at it. The apparatus which he and Cyon first used, and which is figured in his *Arbeiten* for 1866, has been considerably modified by Dr. H. P. Bowditch, and is shown in fig. 10. It

Fig. 10.—Dr. H. P. Bowditch's apparatus for experiments on the heart of the frog. A is the frog's heart. B is a cannula tied into the vena cava, and B' one into the aortic bulb. C, C', and C'' are three glass stopcocks. By C fresh serum is supplied, by C' old serum is let out, and C'' allows the communication between the bent tube B C' B' and the manometer M to be opened or shut at will. D is a glass plate through which the bent tube B C' B' passes. E is a rod ending in a ring into which D is fitted. F is a nut by which the whole apparatus can be moved up and down on the stand G. H is a T-tube. J and J' are two clips to stop the flow of serum from K or K'. K and K' are two fountain-bottles for supplying serum to the heart. K contains pure, and K' poisoned serum. L and L' are bent tubes which convey the serum out of K and K'. M is a small manometer. N is the pen or point which swims on the mercury. The horizontal part is made of glass; the vertical rod of esparto grass, with a small piece of sealing-wax at its lower end. The tracing may be made with ink, or with a dry point on smoked paper. P is a small weight which hangs by a piece of unspun silk from a bent wire, and keeps the pen resting on the paper. Q is the revolving cylinder. R is the clockwork, which is provided with one of Foucault's regulators. S is a table, which can be raised or lowered at pleasure, and fixed at any height by the screw T. V is an India-rubber tube through which the serum is emptied from X. X is a graduated tube into which the serum is allowed to pass after it has circulated some time. V is an India-rubber tube, which is generally closed by a clip, but is opened when the apparatus is to be filled, or when we wish to let down the mercury to zero, in order to draw an abscissa. W is a glass vessel, which fits tightly to the under side of D, and protects the heart from external irritation. Into the two holes seen in D, tubes may be fitted air-tight, and the heart made to pulsate in an atmosphere of any sort of gas.\*

consists of a bent glass tube (C C' C''), which is supported by a glass plate (D). The frog's heart (A) is connected to the ends of this tube by means of India-rubber tubing and two glass cannulae, one of which (B) is tied into the vena cava and the other (B') into the aortic bulb. The tube has three openings, each of which is furnished with a three-way glass stopcock. By means of one of these (C) it can be filled with serum from a reservoir (K or K'), and the stopcock may be so turned as to allow serum to enter the part of the tube above it, the part below it, or both together, or the communication with K may be shut off while the lumen of the tube remains open. By C', the serum which has been already used is allowed to escape, when a fresh supply is given, and C'' allows the tube to communicate with a manometer (M), on the mercury in which a fine pen floats and registers its oscillations on a revolving cylinder (Q). Each time the heart contracts, it drives the serum with which it is filled out of the ventricle, round the tube, and back through the vena cava into the auricle, and at the same time raises the mercurial column in M. The height of the curve traced by the pen depends very much on the amount of serum which the heart contains, being very much higher

\* This apparatus is made by Geisler, Blume's Hof, Berlin. Mr. Hawksley, of Blenheim Street, Oxford Street, has adapted a bobbin and rollers to the revolving cylinder figured above, so that it will carry a continuous roll of paper, and may be conveniently used instead of the kymograph shown in Fig. 7. The instruments which I have already described as necessary for experiments, may be obtained from him or from Oswald Horn, Schiller Strasse, Leipzig.

when the heart is full; and it must, therefore, be equally filled each time, or very different tracings will be obtained. For this purpose I use, as reservoirs for the serum, fountain-bottles, in the mouth of which it always stands at the same level, and, consequently, always fills the heart at the same pressure. One of them (K) is filled with pure serum, and the other (K') with serum to which a certain amount of the drug to be tested has been added.

For the purpose of introducing the cannula into the heart, the brain and cord of the frog are destroyed by a piece of wire, and the animal fixed on its back to a board. A v-shaped incision, with its apex at the lower end of the sternum, and its limbs extending upwards and outwards towards the fore-arms, is then made in the skin, and the flap turned back or cut off. The sternum is then removed in a similar way. The pericardium is next opened, the cut being made while the heart is contracted, so as to avoid injuring it. The apex of the heart itself is then turned upwards, and two ligatures are passed underneath a small vein which runs from its posterior surface to the pericardium. The ligatures are tied, and the vein is cut between them. The pericardium must now be removed entirely from the heart, and the vena cava superior and the right branch of the aorta tied. The vena cava inferior is carefully isolated; a ligature is passed under it; a short and wide cannula tied into it, and another into the left branch of the aorta. The heart is then cut away from the body. Both cannulae are filled with serum, and connected by India-rubber tubing to the ends of the tube c c' c'', care being taken to exclude air-bubbles. The end of the manometer nearest c is filled with serum by opening the clip at v, and allowing all the air and a little serum to escape. The clip is then replaced, and the heart allowed to beat once or twice, with the stopcock c and the clip j freely open, so that it may become full of fresh serum. The stopcock c is then turned so as to cut off the tube c c' c'' from all communication with K; and tracings are then taken, an abscissa or zero-line being drawn under each. The heart is next supplied with poisoned serum from K', and the tracings which it gives are compared with the normal ones. By slightly turning the stopcock c, a greater or less resistance may be opposed to the circulation of fluid, and the effects thus imitated which contraction or relaxation of the vessels would produce in the living animal.

Another apparatus has been invented by Ludwig, and used by Coats in his research on the vagus, in which there is no circulation, the serum being simply forced out of the ventricle at each systole, and falling back at each diastole. It gives, however, very good tracings of the number and form of the heart-beats, and is extremely well adapted for observations on the effects of drugs on the vagus. Its consists of a manometer, K, and a reservoir, A, with which the frog's heart is connected by two cannulae, D and D'. The frog's heart is prepared by destroying the brain and spinal cord, removing the sternum and fore legs, but leaving a large flap of skin, s, to cover the heart with, and then introducing a cannula into the vena cava and aorta, as in the former experiment. Instead of then cutting out the heart, the liver and lungs are removed, and the stomach is cut through the middle; and a glass tube, sealed at both ends, and as thick as the oesophagus will admit, is pushed through it till one end projects at the mouth and the other from the cut end of the stomach. The vagus is thus clearly displayed; and, in order to isolate it more perfectly, all other nerves should be cut away, as well as a part of the pharynx, so that no soft parts may touch it from its exit from the bone to the place where it crosses the aorta. From this point to the heart, it should be left untouched; and the jugular vein should not be tied, so as to leave it undisturbed. The glass tube, j, is then fixed firmly in a holder, L, and the cannulae, D and D', connected with the reservoir, A, and the manometer, K. Instead of the reservoir A shown in the figure, it is perhaps better to use two fountain-bottles. The apparatus is used just like that shown in Fig. 10; and the heart should in this case also be filled so full that a certain tension exists within it even during diastole. The amount of this is shown by the height of the diastolic curve above the zero-line. When the vagus is irritated, the tension during the diastole sinks; but, if its inhibitory fibres be paralysed by atropia, which leaves the quickening ones uninjured, irritation has then the opposite effect, and the tension during the diastole becomes greater and greater till the heart may stand still in firm contraction.

WHAT PART OF THE GANGLIONIC APPARATUS IN THE HEART IS AFFECTED?—In dealing with this part of the subject, we tread on very doubtful ground, for here pharmacology has almost run ahead of physiology; and even with our physiological knowledge of the nervous structures of the heart a great deal of speculation is mixed. We know that the heart contains ganglia scattered through its substance, but found in the greatest numbers in the septum between the auricles and in the auriculo-ventricular groove of the frog's heart, in which they have been chiefly investigated. As the heart, long after it has been

separated from the body, or the apex after it has been cut off from the ventricle, will still continue to beat rhythmically, the cause of the contractions must be contained in itself; and we assume the cause in each

Fig. 11.—Ludwig and Coats' frog-heart apparatus. A is a reservoir for serum. B. A stopcock to regulate the supply to the heart. C. A piece of caoutchouc tubing connecting A and D. D. A glass cannula in the vena cava inferior. D'. Another in the aorta. E. A manometer. F. A piece of tubing closed by a clip, to allow of the escape of serum. G. A fine pen, floating on the mercury in E. H. The frog's heart. J. A sealed glass tube passed through the oesophagus K, and firmly held by a holder L. M. A nut which allows J. to be moved up and down. N. A second holder to support A. P. A stand with upright rod. Q. A flap of skin to cover the heart and prevent drying. V. The vagus.

part to be the cardiac ganglia, and suppose that they are connected by some apparatus which keeps them working harmoniously together, as the different parts of the heart all contract in a definite order so long as it is uninjured. Their action may be rendered slow or quick by nerves passing to them from without, both the retarding and the quickening nerves being contained in the vagus in the frog; while in mammals the retarding ones are found in the vagus, and the quickening ones chiefly in the third branch of the ganglion stellatum (or first dorsal generally joined to the last cervical), although some may also be found in the vagus.

Some physiologists consider that the function of all the ganglia is simply to keep up rhythmical movements in the heart. Others hold that only some of them, found chiefly in the venous sinus and ventricle,

have this function; while others are inhibitory, and restrain the action of the former. These inhibitory ones exist chiefly in the septum between the two auricles. The reason of this supposition is that, when the venous sinus is separated from the rest of the heart, it continues to pulsate; but the auricles and ventricles stand still. When the ventricle is cut off from the auricles, it begins to beat again, but the auricles do not; so that it would seem as if the motor apparatus in the venous sinus and ventricles together could overcome the inhibitory apparatus in the auricles, and keep the heart going; but that this is too strong for the motor ganglia in the ventricle alone, and will not let them go on till they are separated from it, or till it becomes exhausted, which it seems to do after a little, and then both auricles and ventricles begin anew. The physiologists who hold the simpler view, say that this stoppage is only due to the irritation of the vagus-fibres which run along the venous sinus, and that the renewed cardiac contractions are simply due to the irritation passing off. The pharmacologist, however, is not contented even with the more complicated of these mechanisms, but demands a still more elaborate nervous apparatus in order to explain the action of poisons on the heart. The necessity for this has been clearly shown, and a plan of the nerves drawn up, by Professor Schomiedeberg. This apparatus, as it is supposed to be, I have endeavoured to represent in the accompanying diagram. It consists of a ganglion, *M*, which keeps up a rhythmical contraction of those muscular fibres of the heart to which it is connected by the fine nervous filaments, *E*. This ganglion is connected by an intermediate apparatus with an inhibitory ganglion, *I*, which can retard or stop the muscular contractions which *M* produces; and by another apparatus, *C*, with another ganglion, *Q*, which quickens the contractions. *I* is connected by an intermediate apparatus, *A*, with the retarding fibres of the vagus, *V* and *D*, with the quickening nerves, *S*, of the heart.

Fig. 12.—Diagram of the hypothetical nervous apparatus in the heart. *M*. Motor ganglion. *I*. Inhibitory ganglion. *Q*. Quickening ganglia. *V*. Inhibitory fibres; and *S*, quickening fibres from the heart. *A*, *A'*, *B*, and *C*, intermediate apparatus. *E*. Fibres passing from the motor ganglia *M*, to the muscular substance *F*. For simplicity's sake only, one set of motor ganglia has been represented, but other similar ones are to be supposed to be present in other parts of the heart, and so connected with this set that they all work in unison. It must be remembered that this diagram is purely hypothetical; but if this be carefully borne in mind, the sketch will be found of service in remembering and comparing the action of different poisons on the heart.

**INHIBITORY GANGLIA OF HEART.**—We have hitherto included under the terms vagus-ends all the inhibitory apparatus in the heart; but, when we begin to experiment with the heart alone, we find that poisons which such experiments as have already been described would lead us to class together, as acting on the vagus-ends, really act on very different parts of the cardiac nervous system. Thus nicotia, when injected into the blood after the vagi and cord have been divided, renders the pulse slow; but this soon gives way to quickening; or, if the dose be large, quickening may occur at once; and, if we then irritate the vagus, we find that we cannot render the heart beats slow any more than we can after poisoning by atropia. We thus see that, after the irritation which nicotia first occasions in the vagus-ends has passed off, it paralyses them; and we might thus be inclined to think that they acted on the same structures. But, if we give nicotia to a frog, instead of irritating the vagus, we irritate the venous sinus; still-stand of the heart is at once produced; while, if atropia be given, it is not rendered slow at all—showing us that there is some inhibitory apparatus in the venous sinus which has been paralysed by atropia, but left untouched by nicotia. We may substantiate this conclusion by another and extremely useful method of investigation—viz., by administering another poison, and seeing how its action is affected by each of the other two. If we allow a little muscaria to reach a frog's heart, its beats become slower and slower, and at last cease altogether; the ventricles remaining widely distended, just as they would do if the vagus were strongly galvanised. If nicotia be then injected into the frog or mixed with the serum supplying an excised heart, no alteration is observed; and, if nicotia be injected before the muscaria, the latter poison stops the heart just as usual, although the

nicotia may have so paralysed the vagus that no irritation whatever applied to its trunk could act on the heart. But, if atropia be used instead of nicotia, the effect of the muscaria is at once destroyed, and the heart, which was standing quite still, immediately begins to beat. If the atropia be applied first, and muscaria given afterwards, it has no effect. Hence we see that nicotia has paralysed some part of the inhibitory apparatus farther away from the motor ganglia than that on which muscaria acts, while atropia has acted either the same part as muscaria, or some other one which lies between it and the motor ganglia.

Now, as the inhibitory effect produced by muscaria is not developed all at once, but goes on slowly increasing till it makes the heart stand still in diastole, it seems probable that its stimulating action is exerted on a ganglion, rather than on a nerve-fibre; and we therefore suppose that it acts on the inhibitory ganglion *I*. As the action of nicotia is exerted on something farther from the heart than *I*, our first idea is, that it must be the nerve-fibres *V*. But, on applying nicotia to the trunk of the vagus, after fixing the heart in Coats' apparatus, we find, on irritating the nerve above the point, that it still conducts impressions and causes stoppage of the heart; and so we are led to suppose the existence of an intermediate apparatus on which it acts; but, whether or not this intermediate part simply consist of nerve-fibres less protected from the poison than those in the trunk, we cannot say. As atropia destroys the action of muscaria, it may also act on *I*; but the fact that muscaria does not destroy that of atropia would lead me to refer the latter to a part between *I* and *M*, which is represented by *B*. Of what nature this part is, we know nothing; but that such a part exists, is rendered all the more probable by the mutual antagonism of atropia and physostigma. Although this latter poison renders the vagus very sensitive, so that the power of any irritation applied to its trunk to stop the heart is immensely increased, yet it has not the extraordinary power of producing stillstand of the heart possessed by muscaria. Unlike muscaria, however, it has the power of removing the paralysis of the vagus produced by atropia; and, though an additional dose of atropia will again cause paralysis, a second dose of physostigma will again remove it. This difference of action between muscaria and physostigma seems to show that they act on different nervous structures; while the mutual power that atropia and physostigma possess to neutralise each other's effects, indicates that atropia acts on the same structure as physostigma, and consequently on a different one from muscaria.

**ANTAGONISM OF ATROPIA AND PHYSOSTIGMA.**—Atropia and physostigma are thus physiological antidotes to each other; and Fraser has shown that a dose of physostigma large enough to kill an animal may be given to it with impunity, if atropia be administered along with it; and that the animal may be afterwards destroyed by a small dose given alone. It is true, they do not completely counteract each other's action, each one seeming to produce several effects, some of which, and these the most deadly, are neutralised by those of the other drug while others are not so neutralised; and, if enormous doses be administered, those active effects which are not neutralised may become so powerful as to cause death, although they are comparatively unimportant when the dose is small.

**IMPORTANCE OF THIS IN THERAPEUTICS.**—Nevertheless, within certain limits these poisons do antagonise each other most successfully; and this observation seems to me to have a most important bearing on the treatment of such diseases as have their origin in morbid matter introduced into the system, for it shows that it is not always necessary to eliminate a poison in order to remove its effects, but that it may be neutralised and rendered innocuous while still present in the organism; and seems to indicate that, for the treatment of zymotic diseases, we should seek to discover such remedies as will counteract the effects of the poisons on which they depend, and not merely endeavour to quicken their elimination.

**ACTION OF VARIOUS DRUGS ON THE INHIBITORY APPARATUS.**—From experiments which he has made on the excised hearts of frogs with Ludwig and Coats' apparatus, Boehm has come to the conclusion that conia paralyses the terminal filaments of the vagus; nicotia the intermediate structure between them and the inhibitory ganglia; and that others, such as atropia, hyoscyamia, daturia, physostigma, aconitia, delphinia, and veratria, diminish or destroy the irritability of the inhibitory ganglia themselves. It is rather extraordinary to find physostigma in this list; and it would thus seem that the pure alkaloid which Boehm used had a different action from the tincture used by Von Bezold, unless it be that the result depends simply on a difference in the amount of the poison used.

[To be continued.]

## ON HYSTERIA AND ITS INTERPRETERS.\*

By EDWARD JOHN TILT, M.D., M.R.C.P.

THE multitudinous writers on hysteria may be divided into two groups: a comparatively small number of authors consider the word hysteria to be the miserable misnomer of a nervous affection that has no more to do with the womb than with the liver. This group is chiefly composed of more or less eminent men who have never been in the habit of examining women, and therefore know little about the diseases to which they are subject; who, indeed, freely say so, when we meet them in consultation or elsewhere, and who, nevertheless, with singular want of logic, deny that hysteria often depends on diseases of which they profess to be ignorant. On the other side, an imposing majority of writers do not think the old Hippocratic denomination so bad a name, provided it be well understood that the womb only acts by the power which it derives from the ovaries. These writers admit that hysteria is a nervous affection, but they also hold it to be generally caused by some kind of sexual stimulus, either physiological or morbid. This imposing majority comprises almost all those who have made diseases of women the study of their lives—the obstetric authorities of all countries and of all doctrines; and I think it is a very strong presumption in favour of a doctrine when it is held by two men so utterly opposed to each other on many points of uterine pathology as Dr. Robert Lee and myself. The same view is entertained by a host of men accepted as authorities on diseases of women, and who do not practise midwifery.

It is worth while examining what medical students are now taught by men who own they know nothing about diseases of women; and I will give a few samples from the writings of three writers in deservedly high repute.

For Dr. King Chambers, (*Lectures*, 3rd edition), hysteria is another word for "defective volition"; he tells his pupils that hysteria has no more to do with the organ of reproduction than with any other part of the human body; and that it is no truer to say that women are hysterical because they have wombs, than that men are gouty because they have beards.

Dr. Russell Reynolds, quoting from the best work on hysteria, owns that its author, Landonzy, found marked disease of the generative apparatus in fifty-eight out of sixty-seven cases of hysteria, and that in nineteen cases hysteria subsided so soon as the uterine disease was cured; and Dr. Reynolds adds: "but, so far as my experience extends, it is the exception, and not the rule, to find any definite malady, or, indeed, definite complaint in that direction; while in a vast number of cases, there has been absolute health in all particulars relating to the reproductive organs." (*Article Hysteria, System of Medicine*.) He admits, of course, that a disease of the womb may coincide with hysteria, just as disease of the liver may; but he believes it to be more commonly the effect of hysteria than its cause. I am at a loss to understand what this means, unless it be that the womb can be enlarged and ulcerated by hysteria—a position requiring explanation.

Dr. Handfield Jones (*On Functional Nervous Disorders*) teaches that hysteria is characterised by two factors—(1) mobility and excitability of the nervous system; (2) temper; but, in his chapter on hysteria, and in many parts of his valuable book, the complaint is evidently looked upon as the surrender of the patient's will to temper and deception; and he probably gives us his true opinion in a note at page 669, when he says: "A patient I call hysterical who magnifies her ailments; courts sympathy unduly; is selfish, absorbed in her own fancies and troubles; is unreliable or actually deceitful; and has undergone no serious bodily or mental shock or suffering that might occasion nerve-disease." It seems to me this definition applies more to insanity than to hysteria, whereas the diseases are distinct, though the two may combine. It is surely wrong to teach medical students that hysteria is usually a more or less elaborate process of deception, to be cured when the patient likes by an effort of volition.

If I rightly understand Mr. De Berdt Howell, who has paid great attention to the subject, he also considers hysteria to be a form of insanity independent of ovario-uterine causation. My experience has taught me differently; but I quite agree with him when he says that we must not "mistake the helplessness of nervous disease for moral guiltiness, and inflict sufferings on patients we were asked to cure." (*Journal of Mental Science*, vol. xiv, 1869.)

It is due to Dr. Russell Reynolds to state that no one has more forcibly insisted than he has recently done, in the columns of our

JOURNAL, on the present injudicious tendency to depreciate the value of the symptoms that can only be learnt from the record of a patient's inner consciousness, and to only attach importance to objective symptoms. It is, indeed, obvious that to found diagnosis exclusively on objective symptoms, is to treat human beings as if they were dumb animals, and to degrade medicine to the level of veterinary surgery. Could the advance of medicine require this, we should have no right to do so; for the art of healing must ever be partly built on faith, as are all arts that are founded on the relation of human beings one with the other. We must still continue to believe hysterical patients, unless we have strong proof that they are deceiving us or themselves; and when this is not the case, to let the relatives know that we do not believe an hysterical patient, is to sour her temper, damage her character, and perhaps irretrievably blight her future.

Such is the teaching of three of our foremost pathologists; and as a first fruit of their little acquaintance with diseases of women, I beg to remark that they seem ignorant of what is admitted by all gynecologists, that menstrual disorders have a most potent influence to bring on hysteria. They neither deny nor admit this influence; they simply ignore it, as well as own belief in it. The state of menstruation is scarcely ever mentioned in the numerous cases they give, and they do not even seem aware that, by being able to note it as healthy, they would strongly substantiate their own hypothesis.

Neither do these pathologists notice the physiological basis on which rests our belief that diseases of the sexual organs will cause hysteria in women predisposed to it; I allude to the fact that some young women remain healthy until first menstruation; and that although this function be well performed, it brings on an attack of hysteria, because the nervous system is so badly tempered that it is, as it were, poisoned by the healthy stimulus of ovarian influence. They forget that connection has been repeatedly known to cause hysteria in women who had not previously suffered from it; nor do they notice the occurrence of hysteria in young and healthy widows, in whom matrimonial habits have been suddenly suspended, and in prostitutes on their first entering penitentiaries; nor that symptoms similar to the minor forms of hysteria have been noted in men who have given themselves up to masturbation; and also in others who, after having been accustomed to sexual intercourse, have successfully restrained strong desire by a sense of duty during a protracted courtship. They ignore these facts, and seem not aware that, in healthy subjects, the ovaries, like all other viscera, must be fed by their appropriate stimulus, under penalty of disease, sometimes assuming the hysterical type; and as it is thus correct to hold that perfectly healthy ovarian action will evolve hysteria in those predisposed to it, it will be easily conceded that the morbid condition of these organs may likewise do so.

You may ask how it is that some of the best men in the profession should teach such extraordinary pathology; but you will understand it by referring to two long and elaborate clinical lectures on "Hysterical Vomiting", by another most able pathologist, Dr. Hyde Salter, whose death we have now to deplore. In these lectures there was no intimation of the indissoluble connection of vomiting with the physiology and the pathology of the womb, and that vomiting cannot be called hysterical or nervous when it is explained by structural disease of the womb—facts to us so patent, that to attempt to discuss exhaustively hysterical vomiting, and not to mention them, is like omitting the part of Hamlet from the tragedy that bears his name. Nor was it stated that any examination had been made, although the subject of the lectures had many uterine symptoms; and when I wrote to say that this kind of pathology could not bear examination, Dr. Salter admitted, to a certain extent, the correctness of my strictures; and said he had forgotten to mention that he had asked the Physician-Accoucheur of Charing Cross Hospital to examine the patient, omitting to state what kind of examination had been made, for in such a case a digital examination could not be held sufficient.

Here we have a first-rate pathologist seriously at fault, because he lectures on hysteria without knowing anything of uterine pathology; and one of the reasons why he knows nothing of uterine pathology is that, in conformity with the established custom, he asks the obstetric officer of his hospital to examine the patient, instead of examining her himself. It is obvious that, until this form of etiquette is set aside, the men composing the staff of our hospitals have no opportunity of becoming acquainted with diseases of women; and I hope to convince you that this ignorance is a very serious disadvantage to themselves, to their patients, and to the profession.

In the first place, this ignorance of uterine pathology on the part of hospital men in good repute, tends not unfrequently to their misunderstanding the cases they meet with; and I confidently appeal to those who are engaged in consulting practice, whether they do not far too often meet with cases, in which serious uterine disease has been over-

\* Read before the Midwifery Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

origin of our passions in our abdominal organs. Still universal consent shows how strongly they are acted on by emotion—that, in fact, in the viscera are the reflex centres of emotion that stimulate the nervous system to emotional acts.

If I have, therefore, been correct in ascribing hysteria to undue action of the brain as an organ of emotion, a potent cause of hysteria must be found in undue action of one or other of our viscera. It is, no doubt, wonderful that bodies shared by us with the lower animals should not only support the bodily structure, but, by their healthy action on the brain, give lucidity to the mind and warmth to the feelings, making genius more admirable and charity more godlike. This sounds like poetry, but becomes plain matter of fact when we remember how often anger has caused jaundice, and how frequently a host of distressing mental and emotional sensations are due to that state of liver and stomach derangement that we call biliousness, and which doubtless acts by deranging the functions of the neighbouring great ganglia. I have likewise seen repeated attacks of hysteria brought on by biliousness, and their recurrence prevented by such measures as are best calculated to prevent biliary derangement. Such cases are, however, very rare, when compared with those in which the determining cause of hysteria is an ovarian or uterine ailment. The statistics of Landouzy, Brierre de Boismont, and Dubois d'Amiens, as well as the recent assertions of Dr. Crichton Browne, show this to be the case; and those who deny it must bring forward similar masses of equally well digested facts.

What, then, are the diseases of the sexual system that cause hysteria? Not those in which the structure of the ovary and womb are almost destroyed—acutely, as in abscess of the ovary, slowly, as in ovarian tumours and uterine cancer—but, as a rule, the mildest forms of anæmic ovarian uterine disease; showing that it is not the intensity of the disease that causes hysteria, but the fact of its coincidence with a nervous system prone to become hysterical. Thus hysteria is most frequently caused by those limited ovarian lesions that I have described as sub-acute oövaritis, lesions depending on morbid ovulation, and that frequently pass unrecognised under the disguise of diseases of menstruation. Of uterine affections, it is chiefly the milder sort—that are mucous membrane deep—which cause hysteria; and sometimes, by applying nitrate of silver to an ulcerated cervix, we most unwittingly bring on an attack of hysteria, in patients who presented no signs of its being likely to come on, and thus experimentally prove that the two complaints may stand in relation as cause and effect. On one occasion, I thus brought on an attack in a lady, who had never before had one.

How is the brain, laden with emotion, to be brought into contact with the viscera, the reflex centres of our emotions? The late Dr. Todd thought that hysterical delirium and other hysterical phenomena might be explained by toxæmia resulting from retained menstrual blood; but hysterical phenomena frequently arise before there is any menstrual blood to be retained; and Dr. Handfield Jones agrees with me, that with hysteria, as with other neuroses, there is no blood-poisoning. The distance between the brain and the viscera, between mind and appetite, is bridged by the ganglionic nervous system, which unites the viscera by a federal bond of union, and places this federation in intimate connection with the cerebro-spinal system. When the ganglionic nerves transmit healthy impressions to the brain, they pass unnoticed; but a hysterical fit shows how differently nerves and ganglia act when visceral action is more or less diseased.

In many hysterical fits, after a period of incubation, in which the system seems to become more and more charged with excitement, the attack begins by pain in the womb and ovaries. Soon the hysterical aura passes to the epigastric ganglia, and, concentrating there, gives rise to the suffocation and distress characteristic of the disease. Ascending still higher, the hysterical aura reaches the cervical ganglia, giving the sense of strangulation; it then attacks the brain, deranging its functions in ways too numerous to be mentioned, and, at the same time, deranging more or less the functions of the spinal cord, according to the extent of the hysterical aura. For a time pain will thus sometimes in the brain, sometimes in the visceral ganglia, and sometimes it collapses into prostration when the system has been exhausted by convulsions and by critical discharges. It has been published by Romberg and Schulzenberger, to the effect that the phenomena just described by simply pressing repeatedly brought on unconsciousness in a lady, who had never before had one.

The following points in this paper. 1. To show that on and lecturers in our public schools, and highly acquainted with diseases of hysteria, the state of menstruation and the sexual organs should be

accurately examined if they present signs of disease. 3. The best way for neurologists to disperse the clouds that still overhang our knowledge of hysteria and its allies, catalepsy and epilepsy, is for them to study the diseases of the ganglionic nervous system.

## ON A NEW FORM OF ELEVATOR FOR DEPRESSED CRANIUM IN CHILDHOOD.

By FREDERICK WATERHOUSE, L.R.C.P. Lond., and M.R.C.S. Eng., Bolton.

It is a fact well known to us all that, in childhood, irritation of the nerve-centres, proceeding merely from the periphery, often incites severe functional disturbance, whereas direct traumatic violence to the brain may be sustained without much perceptible derangement. To this pathological paradox our treatment of cranial injuries by non-interference is chiefly owing. Except in punctured fractures, we seldom proceed to operative measures, unless the most urgent symptoms demand them; and although there seems to be a gradual reaction setting in, after the period of non-intervention, brought about by the vigorous opposition of John Bell, Abernethy, Liston, and others, to the absurd system of perpetual trepanning, the injury which we inflict by the use of our present instruments often renders our interference unjustifiable.

In reference to the effects of injuries of the head, one fact seems to thrust itself prominently forward, as claiming more consideration from us, as surgeons, than it appears to have hitherto received. We cannot look over a work on psychological medicine without being struck with the number of cases, where the cause of various cerebral disorders, from epilepsy to insanity, is referred to cranial injury received at a period often long antecedent. Mr. Solly, twenty years ago, delivered a very instructive lecture on this subject at St. Thomas's Hospital. An interesting paper, read by Mr. Anthony Bell at the meeting of the Association in Newcastle, bears upon this point. Bucknill and Tuke, and Forbes Winslow, all recognise the gravity of these injuries in their ultimate effects. Indeed the latter, at page 563 of his work on *Obscure Diseases of the Brain and Mind*, says:—"Do we estimate in a manner commensurate with its grave and vital importance, the necessity of watching, with the most scrupulous care, the cerebral symptoms that follow all mechanical injuries of the head? I am satisfied that a vast amount of organic, chronic, incurable disease of the brain and disorder of the mind, can be directly traced to this cause." And again, he says that, after an injury to the head, "the patient recovers without any apparent inconveniences from the injury; but subsequently, head-symptoms exhibit themselves, clearly the consequence of the injury which the brain has sustained many years previously. I am satisfied that the importance of this subject cannot be exaggerated. Repeatedly have I had under my care, cases of epilepsy bidding defiance to all treatment, tumours, abscesses, cancer, softening of the brain, as well as insanity in its most formidable types, whose origin could unquestionably be traced back for varying periods of one, two, five, eight, ten, fifteen, and even twenty years, to damage done to the delicate structure of the brain by injuries inflicted mechanically upon the head."

The character of these injuries, then, being much more grave than we as surgeons are led to suppose, their method of treatment claims proportionate consideration at our hands. Let us briefly take in review—

1. The various forms of depression to which the cranium is liable; and

2. The different instruments which we possess for their remedy.

Depression of any part of the vault of the skull may occur at all ages, but there are peculiar features or conditions which can be presented only at certain periods. 1. In early childhood we often meet with depression without fracture, or the skull is simply bent in. 2. As age proceeds, the bending in cannot occur without fracture; the bone is not detached, but fissured or fractured, depressed or curved in. 3. At maturity there can be no bending; but, if there be depression, there is detachment of fractured bone.

It is to the character of the depression of the second period in particular that I wish now to draw your attention, as being the period during which injuries of the head are, I believe, not only most common, but during which the class of cases mostly occur to which this instrument is best adapted. It extends from the fourth to the fifteenth year, varying of course in different parts of the skull. The variety of fracture accompanying the depression may range from a mere straight fissure to a stellate fracture, in which each triangular piece of bone is depressed at its apex, and still undetached from the sound bone at its base. Splintering of the inner table, which would doubtless be the

sult of such an injury in adult life, seldom happens at this period, on account of the toughness of the osseous structure which also allows of its curving in. The immediate effects are usually overcome without operative measures, and the expectant method of treatment is therefore that generally adopted.\*

With respect to the second point—viz., the instruments we have for the treatment of cranial injuries, I may mention that Dr. W. Newman (*BRITISH MEDICAL JOURNAL*, 1868, vol. i., p. 23), describes those used during the time of the Roman empire; and we do not seem to have much improved upon them. The "modioli" of Celsus and the "cyclici" of Galen were different kinds of trephine. The ancient "terebre" have representatives in our modern necrosis-case, which is doubtless the best place for them. "Lenticulares" for smoothing the rough border left by the trephine, and "raspatories" for scraping off the pericranium, are still to be met with. In Rees's *Cyclopadia*,† published fifty years ago, you will find drawings of many surgical instruments; and the great importance which was then attached to the operation of trepanning is shown by the great number devoted to this subject. Trepan and elevators with tripod stands are not the least formidable-looking weapons.

The power of the screw and the lever are both called into requisition, for the purpose of raising the depressed bone. Paré describes saws like the one introduced by the first Hey of Leeds, which is the most valuable addition we have had for some time to this department. These, I believe, are the principal instruments which have been invented. Elevators on the suction principle have been suggested, but would, I think, be ill-adapted, and unwieldy.

The Elevator, half size; Blade and Cranium, full size.  
a. The blade serrated on its upper border. b b. Sound cranium.  
c c. Depressed cranium. d d. Dura mater.

The instrument‡ here shown is not intended to supersede the ordinary elevator, but to be used in cases where that instrument is inapplicable. For instance, in the second form of depression which I have described, only one side could be raised, unless an amount of calvarium be sawn away, which would doubtless never be replaced. The trephine is of course sometimes necessary in desperate cases; but, like amputation, it is a *dernier ressort*. I do not know what effect on the equilibrium of vital power the shock of removing a circular piece of sound cranium may have: it cannot be *nil*, nor can you consider the operation conservative surgery.

This elevator may be in several forms: one can enter the diploë (if there be any), and thus draw up the bone without entering the cranial cavity at all; the others are inserted between the bone and the dura mater, but do not press upon the brain, if properly made, any more than the ordinary instrument.

When it is to be used, the end is inserted in the fracture (Hey's saw may sometimes be wanted); by half a turn it is brought at right angles

\* In looking over the cases recorded during the last twenty years, to which I have been able to get access, the greater fatality following injury over the left parietal region, as compared with other parts of the skull, has struck me as being remarkable, especially when remembering the pathology of aphasia.

† In the technical department, it is still the most complete work ever published.

‡ Maw, Son, and Thompson, Aldersgate Street, make these instruments.

with the fissure. The bones on each side are drawn up at the same time; the elevator is brought to its original position and withdrawn. Should the edges of the fractured bone tightly embrace the neck of the instrument, it can saw its way out by means of the serrated edge on the shoulders of the blade. This leaves a small aperture, which will afterwards be replaced by bone, whence pus, blood, etc., may issue.

The advantages of this instrument are: 1. Its simplicity of management; 2. It elevates the bone on each side at once; 3. It requires no fulcrum; 4. It can injure no vessels or other structure; 5, and lastly, whilst allowing a sufficient aperture for the escape of fluids which might compress the brain, it takes away none of the natural protecting case of that organ, so that hernia cerebri becomes an impossibility.

In conclusion, if I have succeeded in establishing for the instrument I have designed all the advantages I claim for it, and thereby lessened the risks of operative interference in cranial depression of childhood, I may venture to predict a treatment of these cases, more philosophical and consistent with the dignity of surgery as a science, than that of leaving their cure to Nature alone, with the danger of the future development of many mental and physical disorders, to which so delicate an organism as the brain must ever be liable, when called upon to perform its functions under adverse and abnormal conditions, however much it may have accommodated itself to them. Nature herself, whilst re-establishing continuity in skull-fracture, throws out no provisional callus; but, rather than press upon the brain, leaves it unprotected until the slower process of union by definitive callus can be accomplished. Ought we not, therefore, to take a lesson from her, and use every means in our power, consistent with discretion, to restore the structures to their normal position, and thus hasten repair?

## THE USE OF SETONS IN THE TREATMENT OF STRUMOUS DISEASES.\*

By EDWARD CROSSMAN, L.R.C.P., Hambrook.

I HOPE I shall not unprofitably occupy a few minutes this evening in directing the attention of this meeting to a class of therapeutic agents which may well claim consideration in virtue of its antiquity. I can probably add nothing to what is well known by all here present, but may hope to stimulate some to place more reliance on a remedy which, though well known, is, according to my observation, but seldom used in the treatment of disease.

I shall not trouble you with the pathology of scrofula, or *struma* (the more euphonious word). It will be sufficient for my purpose to say that struma is a state of constitution characterised by the formation and deposit of a peculiar solid material in various organs and structures of the body; that this material is an excretion from the blood, and is the result of defective or perverted elaboration.

In simple inflammation we use sinapisms, or dry cupping glasses, to draw the accumulated blood from the congested part towards the skin. If depletion be necessary, we raise a blister, by which not only is the blood drawn towards the skin, but a quantity of its serum is evacuated. In these instances a temporary derivation only is required; but in struma a morbid material is slowly and continuously formed in, and deposited from, the blood; and, while we endeavour by remedial measures to check the tendency to reproduction, it is necessary to provide an outlet by which the system may be freed from the excrementitious matter. Such I take to be the simple explanation of the action of setons and issues. They do not belong to the class of counterirritants, but to that of evacuants; and, regarding them in this light, I have used them in a large number of cases with the happiest results.

Few writers on strumous diseases fail to mention setons or issues among the various remedial measures; but mention is made of them in a cursory manner, and without that stress being laid upon their employment which, in my experience, it deserves. Moreover, they are generally described as applicable only to the early stage of cases, while in my opinion they are equally serviceable.

The wife of a farmer—one of an eminently strumous during two years consulted various medical men, before consulting me, had received her death-warrant physician. Her left lung contained a large cavity versally crepitant; and she had had several attacks was not consulted with any hope of cure; but, as she was to die, I was called in to watch her end. In this case, I put a seton in her chest, she began to mend. One cut their way out, I put in another; and for six months

\* Read before the Bath and Bristol Branch, Octol

discharge was kept up from the skin, with so happy a result that, fifteen months later, I attended her in a confinement, and she has lived six years since.

A young woman, aged 19, presented herself to me, with extensive tubercular disease of both lungs, which had been running a constantly progressive course for more than two years. She was extremely emaciated, had profuse perspirations, and her legs were oedematous. Her case was one of advanced tubercular bronchitis. I put a seton of six silks in her chest, and at the end of a fortnight the symptoms began to abate. She wore the seton three months, by which time her cough had nearly ceased, and her expectoration was *nil*. She then pressed me to remove the seton, and, upon inquiring the reason of her urgency, she informed me that her banns had been twice asked, and she intended to be married the following week. She was married to a worthless fellow, who used her very badly; and, after an interval of eighteen months, I was called on to attend her in an attack of acute tubercular pneumonia, under which she soon sank.

I will not weary you with the details of cases. My memoranda supply me with the records of thirty-five cases of confirmed phthisis in various stages, in thirty-two of which marked benefit was derived from the employment of setons, while in three the seton was removed without benefit. In none of these cases had I reason to regret the introduction of the seton: emaciation and debility were not increased by the discharge from the skin, but, on the contrary, their progress was arrested *pari passu* with the diminished discharge from the lungs.

Passing to another variety of strumous disease—*strumous ophthalmia*—an issue or seton in the temple is the most effectual remedy, and often the only means of stopping the progress of the disease. Probably in the present day setons and issues are used more often in the treatment of strumous ophthalmia than in that of any other disease; and I take it that it is so because their remedial power can, in the eye, be actually seen and appreciated.

It is not only in the true strumous ophthalmia, attended with corneal ulceration, that setons are of service—they are equally so in all those minor affections of the eye and its appendages which take their origin in a strumous diathesis.

For the relief of an eye-affection, the seton is usually placed in the temple; but a serious drawback to its use in this situation is the scar which it leaves. I find that, placed in the arm or any convenient part of the body, it has an equally good effect.

Some ten years ago, a girl was under my treatment for many months in consequence of frequently repeated attacks of strumous corneitis. Having failed to eradicate the constitutional tendency by medicines, I put a seton in each temple. The result was a complete cessation of the disease; but, having to earn her bread as a nursemaid, she was naturally anxious to get rid of a disfigurement which prevented her from taking a situation, and, contrary to my advice, removed the setons at the end of a month. Not many weeks afterwards, exposure to cold wind brought back the disease, which again assumed a remittent character. Being in a situation at a distance, it was only when compelled to return home that she again became my patient. I then introduced a seton of six silks into her arm, and kept it discharging the whole winter, during which time she was entirely free from the eye-affection, and has never had a serious return since.

A young gentleman seldom passed a month or six weeks for several years without an attack of strumous conjunctivitis. Being first at a private school, then at Eton, and latterly in London, he had been subjected to various plans of treatment. The attacks yielded sometimes to leeching, sometimes to blistering, and at other times to sedative applications; but exposure to cold wind or damp air always induced a recurrence. At last I persuaded his friends to allow me to put a seton in his arm. The suppuration was so severe at first that I had great difficulty in inducing him to retain it; he did so, however, and by degrees fungoid granulations which had sprung up round the points of incision disappeared, and a healthy suppuration was established. From the seton was inserted the ophthalmic attacks ceased; during months he wore it they did not once recur; and for three years he had but the most trifling threatenings of his old

a younger brother of the same family was threatened with. I immediately put a seton of one silk in his

disease, and he has had no recurrence. strumous disease, in which I have used setons with tubercular meningitis. My attention was first directed to me, in company with the late Dr. Symonds, medical practitioner. A child three years of age, apparently of hydrocephalus, was accidentally scalded on large suppurating surface was the result. Dr. Symonds

was fully persuaded that the case was hopeless, and was equally convinced, when the child recovered, that the extensive suppuration turned the balance in its favour. Since then I have treated a considerable number of cases of this disease by the introduction of a seton in the poll, and am fully persuaded that, when the attack is sufficiently prolonged, the establishment of a free discharge offers the best hope of cure.

There is yet another form of struma in which I have used setons with advantage—viz., chronic glandular enlargements. I have found obstinate enlargement of the axillary glands yield to a seton in the arm, or below the clavicle. A seton above the clavicle or in the arm will facilitate the removal of enlargement of the cervical glands; and not long since a most obstinate enlargement of the inguinal glands, which for many months resisted all treatment, eventually yielded to a large seton in the arm, kept discharging for eight weeks. Lastly, I may mention chronic strumous ulcers as curable, when other means fail, by a discharge established at a distant part of the body.

I have avoided extending this paper by the narration of cases, and have omitted the mention of any concomitant treatment. I would not have it supposed on this account that I advocate the use of setons to the exclusion of other remedies. I apprehend the part the seton plays is that of evacuant—distilling, as it were, from the blood the morbid material. It remains to check the reproduction of this material by catalytic remedies.

My apology for calling the attention of this meeting to a subject which is probably so familiar to all present, is the very good result which I have experienced in my own practice from its employment.

#### A SUCCESSFUL METHOD OF TREATING CERTAIN CASES OF DYSMENORRŒA AND STERILITY.\*

By PROTHEROE SMITH, M.D.,

Senior Physician to the Hospital for Women, London.

To treat of the subject of dysmenorrhœa generally, the time to which I am restricted would be insufficient. I shall, therefore, now only speak of that form of the malady which is the result of abnormal constriction of the uterine canal, and which also frequently presents a mechanical obstacle to pregnancy. With this condition, known as obstructive dysmenorrhœa, we are all more or less acquainted, since it is of frequent occurrence amongst the unmarried and the sterile.

The lumbal-abdominal distress, the bearing down and forcing uterine effort immediately preceding the menstrual flux, and the experience of relief when it is established, with the constitutional debility which follows, with consequent neuralgic headaches and pains in the hypogastrium, sufficiently characterise the disease; while chronic and long standing, pains in the *bas ventre*, especially on the left side, continual backache, tenaceous leucorrhœal discharge, with an aggravation of constitutional disturbances, mark the progress of the malady. The diagnosis, however, is complete when, by touch and uterine sound, the constriction of the canal is proved. This condition was described by Dr. Mackintosh, of Edinburgh, in 1844, who proposed as a remedy the use of bougies, so as gradually to effect the dilatation of the straitened passage. This plan of treatment was frequently attended with success, and was, about the same time, modified and improved by the late Sir James Simpson, who used metallic stems two inches and a half long, having a button or bulbous end, by which these "short sounds" were retained and secured. Such means, at times, seemed to answer; but, unless pregnancy soon followed, the constricted parts of the uterine canal resumed their abnormal condition, and called for a repetition of the treatment.

In Dr. Black's excellent edition of the *Selected Obstetrical Works of Sir J. Y. Simpson* (vol. i, p. 679) published this year, is the following paragraph.

"At a meeting of the Edinburgh Obstetrical Society, March 10th, 1847, Dr. Simpson stated that he had now been in the habit for three or four years past of performing the operation of incision of the cervix uteri for obstructive dysmenorrhœa. He first described the operation to the Medico-Chirurgical Society in 1844, and it had latterly been adopted by Dr. Rigby, Dr. Protheroe Smith, Dr. Oldham, and other accoucheurs in London and elsewhere."

The instrument used by Sir James was a kind of *lithotome caché*, by which he divided the strictured part, the incision commencing at the union of the cervix with the body of the uterus, and passing more and more into the substance of the cervix as the instrument was withdrawn, and so dividing its lower edge.

In the year following, I had a double hysterotome constructed in

\* Read in the Midwifery Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

Paris, with two blades cutting laterally; and Dr. Greenhalgh subsequently contrived a very ingenious instrument of this description, by which he proposed to gauge accurately the extent of the incisions on both sides. Dr. Black, however, observes that—"In consequence of the gratifying results sometimes produced by incision of the cervix uteri in obstructive dysmenorrhœa and sterility, that operation became an extremely favourite one with Simpson. Certain risks connected with it, however, and, in particular, its liability to be followed by pelvic inflammation, inclined him ultimately to a rigorous selection of cases, and to the enjoining of recumbency for several days after the performance of the operation."

Stimulated by Sir J. Simpson's favourable opinion, for some time I followed this mode of treatment; but the results, as regards the removal of dysmenorrhœa and sterility, were not such as to convince me of the advantage of its general adoption. On the contrary, in several instances, severe metrocervicitis occurred, together with considerable hæmorrhage, requiring the plug to control it. In others, the painful menstruation was unrelieved, and the patient remained sterile. My objection, however, to the use of the hysterotome was confirmed by observing that, in several instances, it had aggravated the evil; for not only did the patient continue barren, but the original constriction was increased, and, with this straitened state of the uterine canal, the consequent distress was augmented. The pathological condition I discovered by the use of sea-tangle tents. The first case which yielded this information to me was one in which Sir J. Simpson had performed the operation some years previously. For a time, after recovery from its immediate effects, relief from the distressing symptoms was experienced by the patient; but after a short time the dysmenorrhœal sufferings returned, and, as they gradually increased in severity, she was led to consult me. Finding that the uterine sound could be passed only with extreme difficulty through the os internum uteri, I introduced a small sea-tangle tent, which, on the following day, I had considerable difficulty in withdrawing. It was only after continued traction, kept up steadily for nearly twenty minutes, that this was accomplished. When removed from the grasp of the cervix, its form explained the difficulty. At an inch and a half from its proximate end, the tent was not altered in form from its size before it was introduced; whilst above and below this narrow waist, it had swollen to its utmost extent; from this compressed part ran a narrow groove on each side, evidently showing that, at the constricted os internum, as well as longitudinally on each side, there existed unyielding tissue, not only at the points of the original stricture, but also at lines corresponding with the wounds made by the hysterotome, which led me to the conclusion implied in these remarks—viz., that the deep grooves and the longitudinal furrows were the impression of hard cicatrices, the effects of the previous operation. Seeing that the result of incising the cervix, if successful in enlarging the canal, must be to destroy the perfectness of its structure to the extent of the tissue divided by the hysterotome, or that, if rendered unsuccessful by the healing of the wound, it might leave the patient worse than before, from the hardened cicatrix which might follow the operation, I soon adopted a course which I have pursued for many years with a success which encourages me to hope that its announcement will be acceptable to obstetric practitioners generally.

In my lectures, at the commencement of this year, on Flexions, Torsions, and Displacements of the Uterus, at the Hospital for Women, I observed that, "finding sterility and dysmenorrhœa were often benefited by dilating the cervix uteri by the bougie, after the manner advocated by Dr. Mackintosh, and with a view of improving upon the plan suggested, I got Messrs. Fergusson, instrument-makers to St. Bartholomew's Hospital, to make me in 1841 the instrument I now exhibit, after the model of Heurteloup's lithotrite, by which the extent and direction of the uterine cavity was easily measured, and a constriction in any part of the passage as readily overcome." With this uterine dilator, I conceived it might be practicable to dilate permanently the constricted os internum, and afterwards, when necessary, to give the normal shape to the os tincæ by dividing it laterally at the commissures of the labia uteri *per speculum*. I have now adopted this mode of treatment for more than a quarter of a century; and although, in some instances, I have failed to cure, yet I have succeeded in so many others, that I feel warranted in advocating its adoption in the selected cases in which it is eligible. To diagnose such, it has been my custom to ascertain from the history of each case, as well as by a careful physical examination of the uterus, that it is one simply of stricture of the os internum, and narrowing of the cervical canal and mouth. But should there be any inflammatory condition, whether of the mucous lining or of the deeper tissues of the uterus, or any thickening or induration of these parts, it is essential to success, however tedious the process may be, to remove such morbid conditions before adopting the *extension forcée*, by which the stricture is to be overcome.

The plan which I then pursue is, first to prepare the patient by a purgative dose, and by abstinence from local excitement, and from alcoholic drinks, or much animal food. When hyperæmia exists, I scarify laterally the labia uteri repeatedly at the commissures of the labia, by which the vascularity of the organ is reduced, and the shape of the os tincæ, when constricted, is improved. After accustoming the uterine canal to bear a metal bougie, which should be repeatedly and daily introduced, and increased in size until that of a No. 10 catheter can be borne without any pain, then the uterine dilator may safely be employed. It will be seen that this instrument consists of two short blades, two inches and a half long, the inner being continuous with the sliding shaft, with which it is nearly at a right angle, having at its proximate end a screw worked by a nut so as to mark precisely, by an index on the handle, the extent of dilatation employed. This should be used at first cautiously about every second day, always ceasing to screw as soon as pain is experienced. This is immediately relieved by a turn or two of the screw the reverse way.

It will be found, in a short time, that the uterus becomes accustomed to the dilatation, when it may be employed to a greater extent; and in the course of a few days or weeks, as the case may be, a forced dilatation to the extent of an inch or an inch and a half may be used with impunity. After this it will only be necessary to use the dilator daily for two or three days, and afterwards at longer intervals, to keep the parts open till they permanently heal in the state of distension effected by the operation.

Should any congestion or inflammation result, scarifying at the commissures of the labia will relieve by free bleeding, whilst, at the same time, the os tincæ is made to assume a more open, and, therefore, a more normal shape. I prefer, generally, to effect this by the repeated use of a small scimitar-shaped knife, as I find that by so doing the risk of inflammation is diminished, and it prevents cohesion of the cut sides of the labia uteri, both which accidents occasionally attend the operation when performed at once by a hysterotome. When preternatural shortness of the uterus, from original malformation, exists, the operation is contraindicated; also when stricture depends on endometritis; when, otherwise, metritis or metrocervicitis is present; when there are fibroid tumours causing inflammatory adhesions; when dysmenorrhœa is characterised by deciduous membranes; when there are conical hypertrophy and elongation of the cervix; when there is globular enlargement of the anterior labium uteri, embraced by the posterior lip in the form of a crescentic membrane; and when displacements and dislocations of the organ complicate the case—these and all other organic diseases which may attend this malady should be removed prior to the adoption of forcible extension by the dilator.

Time would fail me, were I to attempt to illustrate these remarks by a review of all the cases in which I have employed this mode of treatment. It must here suffice to remark that, I have seen this practice followed by complete success in many instances, from amongst which I would quote the following extreme, but successful cases of dysmenorrhœa and sterility, treated by forcible extension and incision of the labia uteri.

CASE I.—A lady, aged 41, after sixteen years of married life without pregnancy, has since given birth to two children.

CASE II.—A lady, aged 37, her husband hemiplegic from his youth, married thirteen years without family, and now has a living child.

CASE III.—A patient, aged 39, married twelve years, and barren, became the mother of a living child.

CASE IV.—The wife of a clergyman, aged 28, having been sterile for six years after marriage, was delivered of a living child.

CASE V.—A resident in a distant colony, married fifteen years, and barren, aged 38, became pregnant, but miscarried, in consequence of over-exertion at the second month of utero-gestation.

CASE VI.—A delicate lady, aged 29, married nine years, but never pregnant, became so, and had a living child, followed by a second two years after.

I select these few cases from a large number, because in all there existed more or less dysmenorrhœal symptoms, and three of them were complicated by considerable structural disease, which had first to be removed before the plan of treatment I now advocate was adopted.

In this paper I have endeavoured, as far as possible, to confine my observations to facts capable of demonstration; and I hope the experience of other members of this Association may confirm my own conclusion that forcible distension of the constricted os internum and incision of the os tincæ only, in the manner described, in cases of obstructive dysmenorrhœa and sterility, is preferable to the operation by the hysterotome. The former is attended with less risk; and, with this impunity, it offers greater success, with the further advantage of leaving the uterine tissue, excepting at its extreme mouth, without lesion.

## CASE OF HYDROCEPHALUS IN AN INFANT TEN WEEKS OLD, RESULTING IN RECOVERY.

By J. THOMPSON DICKSON, M.A., M.B. Cantab.,  
Physician to the Infirmary for Epilepsy and Paralysis.

THE following case is of interest from two distinct points of view; its aspect in relation to nomenclature, and its appearance in relation to pathology. According to our received nomenclature, the term acute hydrocephalus is synonymous with tubercular meningitis; whilst all other forms of cerebral affection associated with effusion, except sun-stroke, are included under the head of chronic hydrocephalus. "Chronic hydrocephalus", however, would not convey a notion of the acute, but non-inflammatory, affection, the particulars of which I am about to detail; still less would "acute hydrocephalus" express the disorder if a tuberculous disease be thereby understood. I have, therefore, excluded adjectival distinction in giving a name to the case; which, though it did not, perhaps, pass beyond the stage of congestion, yet properly belongs to the group of cases characterised by watery effusion, to which the term "hydrocephalus" is rightly applied.

Whilst on a visit in Scotland lately, I was one day asked to see a female infant, ten weeks old, who, I was told, had been asleep for twenty-four hours—viz., from about 3 P.M. on one day until 3 P.M. the following day. I found her, about an hour afterwards, not only still sleeping, but almost comatose. Her brow, from time to time, was corrugated and contracted, and she was groaning occasionally. Her skin was warm, but not fevered, and her pulse, which was about 100, was rather feeble; her bowels were constipated, though shortly before the sleep commenced she had passed some green stools. Her abdomen was tense, but evidence of pain in it was wanting; and vomiting was absent. The case, in fact, very much resembled spurious hydrocephalus, except that the infant's head was intensely hot, and the fontanelles were bulging and very tense. On inquiry, I learnt that the child had once before had a somewhat similar attack, but of shorter duration; that the mother was exceedingly delicate, and was unable to furnish sufficient breast-milk for the child's support; and that cow's milk was obtained with so much difficulty, that Indian corn-flour had been substituted as part of the infant's diet. So profound was the slumber, that I doubted much whether the child would wake again. The feeble pulse at once contraindicated depletion, although the head-symptoms were desperate; and I merely prescribed a grain of subchloride of mercury to be placed on the infant's tongue, with a little white sugar, and cloths dipped in water or spirit and water to be applied to the head. I also ordered that the calomel was to be repeated. After some hours, the bowels were relieved of a dirty green stool; and, after twelve hours, the child woke up, and took some milk, but immediately fell sleep again. A second powder was then administered, and the bowels were afterwards moved twice. In about six hours the child again awoke, and appeared much relieved; the bulging of the fontanelles had disappeared, and the head was no longer inordinately hot; the skin was natural; and, with the exception of a feeble pulse and occasional vomiting, the little patient was convalescent. I of course ordered that all farinaceous food should be discontinued; but the mother's precarious health and the inadequate supply of her breast-milk had to be considered. The mother's means were not sufficient to afford a wet-nurse, and the supply of cow's milk was irregular as to quantity, and only to be obtained in the evening. I therefore restricted the mother's feeding to the daytime, and ordered that the evening and night feedings should consist of cow's milk, diluted with water and sweetened with sugar of milk. The improvement in the child's condition was soon apparent; but, in a week, the symptoms returned. The sleep of the second attack, however, was not so long continued as that of the first, lasting only from one night until the next, and ceasing soon after the bowels had been relieved by calomel. I saw the child in a third attack, the duration of which was less than those preceding, and it yielded to the same treatment as the former. I recommended the mother to use her powders, not sparingly, whenever the bowels became irregular; and I have had the satisfaction of learning that the child has not since had any return of alarming symptoms.

REMARKS.—In infancy, the brain is a rapidly maturing organ, and is, in consequence, very liable to hyperæmia; and this condition may be induced by very slight exciting causes. In this case, the indigestible food which had been given was alone a sufficient exciting cause. The case was clearly not one of arterial congestion; for, with the exception of heat of the head, febrile symptoms were absent. Neither was there tuberculosis; for not only were inflammation, convulsions, and extreme pain in the head absent, but tuberculous history was altogether wanting.

On the other hand, the external veins of the head were full, and the scalp and face were of a dusky blue colour.

It seems more than probable that, whenever the ingesta irritated, intestinal hyperæmia was set up, and with it portal congestion; and these together either directly delayed the general circulation by which the brain and its vessels immediately become over full; or else, from the sympathy between stomach and brain, the moment the former rebelled against the unnatural food put into it, the latter expressed its sympathy by disturbed action, the venous congestion being only a part of a pathology which we are as yet unable to define. The condition of venous congestion is highly favourable to the induction of serous effusion; and such may or may not have occurred in the case of the child. Possibly the stage of engorgement was not perfected; the fluid effused being so small in amount that, save for the liability of recurrence, it did not seriously damage the brain. But I am convinced that, if more or less active measures had not been adopted, the child would either have died from the pressure, or by this time have been confirmed hydrocephalic, unless meningitis had supervened, as at one time appeared imminent.

## A CASE OF PARALYSIS DURING PREGNANCY.

By HENRY M. MADGE, M.D.

CASES of paralysis during pregnancy are rarely met with. Dr. Churchill, after an extensive search in consequence of a case occurring in his own practice, succeeded in finding only thirty-five cases of various forms of paralysis connected with pregnancy; twenty-three having occurred during pregnancy, and twelve soon after delivery. None of them, however, were of that peculiar form of paralysis which attacked my patient. As far as I can learn, I believe her case to be unique.

Mrs. S., aged 36, stout and robust, and of generally good health, had been married several years and had two children. The death of the youngest, when eighteen months old, caused great grief to the mother; and soon afterwards (in September 1867) she presented symptoms of early pregnancy—cessation of menses, morning sickness, and enlarged breasts. The sickness increased; and, in about three months, it generally continued throughout the day. She was naturally very stout, with thick abdominal walls; and it was partly owing to this that neither Dr. Greenhalgh (who was called in) nor myself could satisfy ourselves by examination that pregnancy existed. Shortly after this the patient began to complain of severe pains in the hands and feet, which soon became excessively sensitive and painful. This condition did not extend above the wrists and ankles. After a few weeks this hyperæsthesia ceased, and was succeeded by anesthesia. There was also entire loss of motion—in fact, complete paralysis of hands and feet. Dr. Radcliffe was now called in, and, after examination, came to the conclusion that the case was one of congestion of the grey matter of the spinal cord, and that the prognosis was unfavourable. He ordered small doses of ergot, which the patient took for several weeks without, however, any perceptible benefit. In the meantime the sickness disappeared, the breasts became smaller, and the general health improved. Throughout the case there was little or no headache, nor tenderness along the spine: counter-irritation, however, was freely used. The pulse and temperature were nearly always normal. The urine was sometimes limpid and abundant, sometimes scanty and thick with urates, but always free from albumen. The patient's mind was often confused, and her memory impaired. Notwithstanding her protracted illness and thoroughly helpless condition, she was generally in tolerably good spirits. Various tonics, nervine and otherwise, were used; but the paralysis continued and seemed likely to become permanent. In May, 1868, no perceptible change having taken place, faradisation was commenced, and applied about a half an hour twice a day; sometimes one pole was held or supported in the left hand and the other applied to the right foot, and *vice versa*; sometimes one was applied to various parts of the spine and the other to the extremities. At first she could not feel the current in the hands or feet, but above the ankles and wrists she could feel it readily, and the contractions and twittings of the muscles were easily seen. The remedy was perseveringly applied for increasing periods, and sensation began to return in the hands and feet just two months from commencing it. Motion was much slower in returning. The middle finger of the left hand and the second toes of both feet were for a long time helpless: at length, however, she was able to move them, and her recovery now was nearly complete. In August, 1868 (about eleven months from the commencement of the illness), she was able to walk down stairs without assistance. Shortly afterwards, a very unexpected occurrence took place. Towards the end of August she was delivered of a dead fœtus, of about

four months, enclosed in its membranes. The liquor amnii was muddy, but not fetid; and the fetus was of the same dark muddy colour. It had to all appearance been retained in the uterus many months, but had been preserved from decomposition by the liquor amnii. There was very little loss of blood; and the patient made a good recovery.

REMARKS.—Were the symptoms caused by the pregnancy? Ollivier has written a work on this particular form of paralysis. He had seen only one case, and that had no connection with pregnancy. He attributes it, like Dr. Radcliffe, to "congestion of the grey matter of the spinal cord." Might it not, however, be possible for pregnancy to produce this identical congestion and consequent paralysis? Whatever may have been the cause in my case, I feel indebted to Dr. Radcliffe for having pointed out to me its true pathology. It is evident that there was something more than mere hysterical or functional disturbance. Dr. Churchill is disposed to attribute all cases of paralysis during pregnancy to the presence of albuminuria; but that had certainly nothing to do with the case I have related. With regard to treatment, if it had been possible to prove the existence of pregnancy—assuming that condition to be the cause of the paralysis—it seems plausible enough, that it would only be necessary to remove the cause. In several of the cases, however, collected by Dr. Churchill, the paralysis disappeared during pregnancy without interfering with gestation; therefore, in such cases, I do not know that the induction of labour should be too readily adopted; though, in some special cases, no doubt it would become necessary. The ergot was given on account of its supposed contractile effects on the smaller vessels, thus lessening congestion; but it might also have had some effect on the uterus and its contents. Did the case take a favourable turn because of the death of the child? I hardly think so; because, in several of the cases, the patient recovered from the paralysis before delivery, and afterwards gave birth to a living child. Did electricity cure the patient? This question I am unable to answer; but, in a similar case, I should certainly use it again, for, besides its possible therapeutic effects, it serves to occupy the patient's time and attention, and to introduce a gleam of hopefulness when there is much to cause depression and despair.

## INVERSION OF THE UTERUS.

By JOHN THOMPSON, M.D., Bideford.

LATE in the autumn of 1848 I was summoned to the wife of a respectable farmer residing some miles from Bideford, who had been for more than forty-eight hours in labour under the management of a midwife. The presentation was, at first, believed by the nurse to be footling; but at length the hand protruded, and then her error was evident. Finding delivery impracticable, she sent for me; and, on my arrival, I found the foetal arm protruded up to the armpit, and discoloured throughout. The uterine action being very powerful, it was clear that there would be much difficulty in turning the child and completing delivery. After explaining the danger to the husband, and sending for a professional friend in case I should need assistance, I bled the patient to about twenty ounces, and gave her a drachm of tincture of opium. Then, lubricating the back of my left arm and hand, I slid them little by little up the vagina and uterus to the feet of the child. Notwithstanding the bleeding and the large dose of opium, the uterus made such resistance that my hand had to sustain pressure, causing cramp and great pain, before I could effect my object. After about an hour delivery was effected, the child being dead; but the mother was uninjured. The placenta came away without difficulty, and, though there was rather free bleeding, neither exhaustion nor other evil consequence ensued. The arm and hand with which I operated were so much injured that several weeks elapsed before full power and normal feeling were restored. Had I known the full value of chloroform at that time, its administration would perhaps have been substituted for bleeding and opium, and have prevented the punishment I personally sustained.

My patient made a good recovery, and in the next year retained me to again attend her. The presentation in this case was natural; but the placenta was retained, and I had to introduce my hand into the womb to remove it. She was subsequently confined in the years 1850, 1852, and 1853, which shows that fecundity had not been impaired by the severity of her confinements. There was some difficulty in each labour, either a faulty presentation or retained placenta, or the birth was premature; but there is no object in giving details of these cases.

Her last labour was in December, 1853. The presentation was natural; she had arrived at her full time, and delivery took place in a few hours. After handing the infant to the nurse, who then retired from the room, I applied my hand to the abdomen of the mother, but, instead of the usual

uterine tumour, there was a vacuity such as I had never before met with. As I had not attempted to withdraw the after-birth, this seemed strange; nevertheless, believing that inversion of the uterus only occurred where traction had been exercised on the funis, it did not strike me that it could have happened here. On examining the vagina, I found the placenta, and at once attempted its removal. In a few seconds it came away with an unusual sort of plunge as if a coagulum had emerged with it, and I tried to remove the mass from under the bedclothes to the ordinary receptacle, but found myself hindered by a band which appeared stouter than the ordinary membrane, and which was, in fact, the inverted vagina. Lifting the bedclothes, I was astonished to observe the after-birth and womb both escaped together, the latter completely inverted, and having the placenta partially attached. There was no bleeding, nor had much blood come away by the vagina. Promptly taking off my coat, and baring my arm, I first peeled off the placenta—this was done with great facility. No blood flowed from the uterine surface. Then, taking the uterus in my right hand, I passed it up the vagina, and, bending my fist, pressed nimbly against the fundus (my left hand meanwhile supporting the abdomen) and in an instant restored its position. My right hand passed into the uterine cavity, where I allowed it to remain till contraction came on, and it was only withdrawn when uterine action became decidedly expulsive. The patient, during this time, experienced no shock in her system; she lost but little blood, and subsequently made as good a recovery as she had done in any former confinement. Since that time she has not been pregnant, though she has had good general health, and looks ruddy, vigorous, and cheerful.

Two practical views derive support from the facts of this case; the first, that inversion may, and sometimes does, take place without interference on the part of the attendant; the second, that reinversion may be readily effected, if the manipulation be prompt and well-directed. Formerly, it seemed to be the opinion of the profession that inversion of the uterus always indicated a faulty interference on the part of the practitioner—perhaps the view now generally held is that this is only the most frequent cause. On this point I may refer to the section on Inversion of the Uterus in Dr. Tyler Smith's *Manual of Obstetrics*, where it is pretty fully discussed. His views are concluded with the remark, that, "Owing to the prevalence of the mechanical idea respecting its origin, obstetricians have often been blamed most unjustly in cases of *post partum* inversion." The ease with which I restored the displacement was the most remarkable feature in the case; it contrasts strikingly with the distressing failures related in the columns of the different medical journals. The reason for this difference seems to me clearly attributable to the fact of my having acted at once. It is noticeable that in nearly every unsuccessful case the accident has occurred for some time before attempts have been made at reduction—in the majority it could not then be remedied. A reason for delay to procure professional assistance is afforded when, as in the instance I have described, the mouth of the uterus contracted over the course of the uterine vessels and prevents hæmorrhage, but it is to be remembered that this is the very case likely to give the most resistance to reduction if delay be allowed. Dr. S. Merriam, writing in the *Medical Times* of July 12th, 1851, says: "It cannot be too urgently impressed upon the mind that one of two consequences must follow, unless the complete reinversion of the uterus is soon effected—either the profuse hæmorrhage will destroy, or the hæmorrhage will be stayed by the contraction of the uterus in its misplaced condition, and this contraction which prevents the further loss of blood, will also render impossible the reinversion of the womb." In the operation for reinversion, time seems to be the essence of success. As in my patient procidentia uteri was combined with inversion, the diagnosis was very easy; but had the placenta separated from the womb in the vagina, and left it there inverted, there was nothing about the patient's symptoms that would have indicated so grave an accident. The diagnosis must have rested on the perception of the vacuity in the abdomen, where the uterus is commonly felt. This was so striking that I should, in any future case, instantly have my suspicion on pressing my hand well down on the abdomen. This point derives additional importance from the remembrance that many cases of inversion have escaped detection, and that the question of a vaginal tumour being a polypus or an inverted uterus has, in the chronic condition, puzzled some of our most experienced practitioners. A careful examination through the parietes of the abdomen soon after delivery would probably have decided the matter. It has been stated by Cruveilhier, in opposition to the views of Dr. W. Hunter, that the internal surface of the uterus after delivery is completely denuded of mucous membrane, and left very much in the condition of an amputation-stump. Though this view, coming from so great an anatomist, long obtained credence among a large number of the profession, its truth has of late been questioned; and a paper was read before the Obstetrical Society of London in May 1862, by Dr. Matthews Duncan, in which he contro-

verted the views of Cruveilhier. In the case that I have just detailed, I took notice that the internal surface of the uterus was covered generally by a fine mucous membrane, very smooth, thin, and much resembling in colour an inflamed facial lip. There were sundry spots, in size like finger-points, where mucous membrane was entirely wanting, and the muscular substance looked like the raw muscle of the amputation stump. The edges of these spots were irregular and ragged, and by them I was enabled to see that the mucous tissue was thin and delicate. Looking at the surface generally, it was clean and free from bloody points. Probably the constriction which restrained hæmorrhage also prevented gummy exudation.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### GUY'S HOSPITAL.

OPERATIONS, DECEMBER 8TH, 1871.

*Necrosis of the Lower End of the Humerus.*—Mr. COOPER FORSTER operated on a girl fourteen years of age, for necrosis of the lower end of the right humerus. About four years ago, she was hit by her brother on the right elbow, and the arm became painful and swollen. A year after the injury, some fistulous openings appeared about the joint, which became stiff; and she was under the necessity of wearing a splint with a cap which allowed the openings to be dressed. There was at the time of operation some slight rotation of the radius; but the arm could not be bent or straightened. Mr. Forster removed two pieces of necrosed bone, each about an inch in diameter; but did not attempt to render the joint movable or of any further service to the girl.

*False Ankylosis of the Hip-joint.*—Mr. BRYANT made an opening in the neighbourhood of a boy's left hip-joint, and took out a small piece of necrosed bone from behind the head of the femur. The joint appeared perfectly stiff and ankylosed before the administration of chloroform; but the fibrous adhesions were to some extent broken down, and the joint rendered more moveable, under the influence of the anæsthetic. Mr. Bryant quite expected that he would have to take out the head of the femur; but, finding the joint so moveable under chloroform, he thought it only necessary to relieve it by manipulation.

*Stricture with Fistulous Urethra.*—An interesting case of strictured and fistulous urethra was operated on by perineal section. J. H., a labourer, aged 37, had suffered fourteen years ago from gonorrhœa, which lasted several months, and for which injections were used. He had congenital scrotal hernia. Three years ago, a lump formed in the under part of the penis, which increased in size and hardness until it reached the size of a hen's egg; and sinuses then formed, from which the most part of his urine flowed on micturition. This lump was removed at Maidstone Hospital, and a part of the urethra was taken away. Mr. BRYANT was unable to pass any sound or probe into the bladder. He could not, therefore, perform Syme's operation for stricture. He was able to pass a grooved probe through the fistula; and, hitting upon the anterior portion of the prostate gland, he cut down upon it through the perineum, and then cut forward, dividing all the tissues down to the probe (Mr. Cock's operation). He thought that, if this proved successful, a plastic operation might close up the fistula in the urethra.

He next proceeded to examine a case of skin-grafting in an extensively ulcerated leg; but the grafts were all dead, and no good results had been obtained.

#### KING'S COLLEGE HOSPITAL.

OPERATIONS, DECEMBER 9TH, 1871.

*Cancer of the Breast.*—Sir W. FERGUSON amputated the scirrhus part of a woman's left breast. She had been operated on for scirrhus of the same side nine months before; but the disease had returned, although not to any great extent. Sir William Fergusson thought another operation might give further immunity to the patient, and answer the purpose better than caustic or any other application. Up to the present day it is, he said, a vexed question among surgeons whether the whole breast or only the diseased part should be removed. He believed it was always best to take away only the disease, and leave as much of the breast as possible to the patient—especially the nipple. In this case he left the nipple.

*Amputation of the Middle Finger.*—Mr. HENRY SMITH amputated the middle finger, supposed by the patient to have been poisoned with

copper. The three joints being diseased, the whole finger was removed, with the head of the metacarpal bone. He recommended the removal of the head of the metacarpal bone, even though undiseased, whenever the middle finger had to be amputated, but not when any of the other fingers were taken away. The reason he assigned was, that, the other fingers being closely approximated, the hand was rendered more useful.

*Varicocele and Hernia.*—Mr. WOOD applied his spring tractor for varicocele to one case, and operated for the radical cure of hernia in another—explaining in detail the steps to be taken in such operations. In reference to the latter operation, he mentioned that the patient received the hernia as an inheritance from his mother, and that this was frequently the case. In many cases where hernia itself is not inherited, there is a tendency to it from the inherited patulous and weak state of the rings. He had now operated on two hundred patients, with a bad result in only three—an unprecedented success in the treatment of disease of this kind; but he attributed his success in no small measure to his never attempting the operation on those suffering from any serious organic disease, or in a debilitated state of health.

#### NATIONAL HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

A CASE OF PARALYSIS AGITANS.

(Under the care of Dr. H. CHARLTON BASTIAN.)

THOMAS S., a tall, thin man, aged 51, a draughtsman, again came under observation on November 28th, having previously been an out-patient under Dr. Bastian's care from April 1868 to March 1869. On first presenting himself, he said that four years ago, whilst on a surveying tour, he was much exposed to cold and wet, and remained in damp clothes for several days. A week afterwards he felt slight twitchings of the left fingers, which gradually increased, and extended to the whole of the left upper extremity, though the parts above the elbow had been only implicated during the last eighteen months. For the last four months he felt twitchings of the left toes, more especially when the weather was damp. He never felt an ache or pain in either limb, in the head, or in the back; and there was no tenderness in the latter situation. The left arm had gradually become weaker. His general health and appetite were good. There was no cardiac bruit; no history of syphilis. The patient exhibited constant twitching movements of the fingers and hands, and occasional movements of the same kind in the fore-arm and arm. When the two arms were compared, there seemed to be no wasting of the left, though the circumference of the largest part of the fore-arm was half an inch less than that of the opposite side. His grasping power, measured by Duchenne's dynamometer, was 11 deg. on the left and 42 deg. on the right. The patient stated, however, that he had always been notable for a great difference in the strength of the two arms; and, as it was found that the left foot and the left arm (more especially the former) were slightly smaller than the right, it seemed most likely that the patient's own notion was correct, as to the existence of a congenital weakness of this side. The smaller size of the fore-arm might, therefore, have been in part due to a deficient development. The electro-sensibility was found to be slightly impaired in the fore-arm, though the electro-mobility seemed to be unaffected. Sensibility was not otherwise impaired. He was ordered eight-grain doses of iodide of potassium in infusion of calumba three times a day, and drachm doses of cod-liver oil night and morning. Two months and a half afterwards he had decidedly improved—sometimes passed a whole day without any shaking (this being in the month of June); whilst the twitching of the toes had ceased. His attendance became irregular soon after this; but when seen in the following December, his grasp, measured by the dynamometer, was 15 deg. on the left and 60 deg. on the right.

On again making his appearance at the hospital, on November 28th, he stated that he had ceased to attend about two years ago, thinking his malady incurable; although he had felt better whilst taking the medicine. He had not followed any occupation since, and had lived very plainly, getting only a very small quantity of animal food at intervals. He came to this hospital again because he had been feeling much worse during the late cold and the wet weather. A similar exaggeration of symptoms had been frequently noticed—cold dry weather not affecting him so much. Eighteen months ago, the right arm began to be affected, and continued to get worse (in the same order as the left). The right arm and hand were now rather worse than the left. The legs shook much less than the arms, and the right leg only when in certain positions. He walked fairly well and steadily; but directly he began to walk the twitchings of both hands and fingers became much more marked. The twitchings were also increased by mental acti-

vity, by surprises, and even whilst replying to any ordinary question. The patient himself remarked that he was always most comfortable when lying on his back, with his mind also at ease. Under these conditions his limbs would continue at rest for thirty minutes at a time; and he was able occasionally even to move and replace them without the occurrence of any twitchings. He was always most easy and quiet for an hour or two in the morning after getting up. He slept "remarkably well". There was still no trace of pain in the head or limbs. His memory "was excellent". There was no emotional weakness. He was still cheerful in disposition. His sight and hearing were good; the pupils were of an equal medium size, but sluggish. Micturition and defecation were not disturbed. On measurement, the left arm was now found to be half an inch less, and the fore-arm one inch less, in circumference than the right. Measured by the dynamometer, his grasp was 14 deg. on the left and only 35 deg. on the right side. He was again ordered eight-grain doses of iodide of potassium three times a day, with two drachms of cod-liver oil night and morning, and directed to lie in the recumbent position as much as possible.

REMARKS.—Although presenting no very unusual symptoms, the case is interesting in many respects—on account of its mode of origin, the slow extension of symptoms, the perfect freedom from pain, and the congenital weakness of the left side, which was first attacked. The exacerbation of symptoms in cold and wet weather is common in this and other allied affections. The great mitigation of symptoms after the power of the nervous system had been restored by rest—their almost complete absence, in fact, for two or three hours in the morning—seemed to point to minute nutritional defects in certain portions of the nerve-tissue, rather than to obvious and permanent degeneration. Dr. Bastian thought that the exaggeration of the twitching movements by simply standing or walking, combined with a like exaggeration by mental action, seemed to point to the pons Varolii as the most probable seat of disordered activity: this being also the region in which structural changes have been chiefly found in more severe cases of paralysis agitans. The progressive diminution of muscular power in the limbs affected is commonly met with, though it is not often associated with actual wasting of muscles, other than what may be accounted for by disuse. The indications were to obtain as much rest as possible in the recumbent position, and more nourishing food. Dr. Bastian had seen much good result in similar cases from the use of cod-liver oil and iodide of potassium.

#### MIDDLESEX HOSPITAL.

##### SULPHATE OF IRON IN ERYSIPELAS.

MR. HULKE, at this hospital, has lately tested the great efficacy of iron sulphate in extensive erysipelas. He uses it as a lotion of ten grains to an ounce of water, applied warm on a rag; and believes it acts as a local styptic, astringent, and sedative, as well as a constitutional tonic. In circumscribed erysipelas on small surfaces, he applies the ordinary coating of collodion and castor-oil. He deprecates the application of flour on any part, as a source of dirt, blebs, and maggots. So many cases of erysipelas have lately occurred in and around the hospital, that he thinks it must be caused, in wounded and weak patients, by a deleterious atmospheric influence. What the nature of this influence is, he is unable to say.

## REPORTS AND ANALYSES

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### CRAIG'S SOLID PEA-SOUP.

WE have had forwarded to us a specimen of solid pea-soup (Craig's patent), consisting of beef, peas, savoury herbs, and seasoning. It is sold in very convenient packets sufficient for one pint of soup, and requires only half an hour's preparation. It makes a most nourishing and agreeable soup, and our trial of it fully bears out the pretensions advanced on its behalf by the manufacturers, Messrs. Hewitson and Co., Harp Lane. We consider it to be a valuable addition to our articles of diet, and believe that its convenience and portability will be recognised by all who use it.

## BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 16TH, 1871.

### THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

THE loyal and profound anxiety with which the nation regards the trying and alarming illness from which the Prince of Wales is suffering has, during the week, overwhelmed all other considerations. It cannot be said that the anxiety is excessive, or that the alarm has been in any degree unfounded.

Typhoid fever of a severe type is, as has throughout been very deeply impressed upon the public mind, a most insidious, treacherous, and threatening disorder; but the Prince's physicians have had to battle with a form of the disease which is not of the ordinary type, but which has presented peculiarities, and is now undergoing a development, of a very unusual kind. They have had to interpret, and it is needless to say how skillfully and cautiously they have done so, one of the most intricate series of problems in disease which can present itself. Aided by a large experience, and by a known clinical sagacity of high order, they have not been at a loss to find the key to a series of phenomena which have before now proved baffling to highly trained intellects. We need hardly recall to our readers the usual regular sequence of events in a severe case of typhoid fulfilling the fourth week of its course. Barring certain complications, which we may dismiss from consideration in discussing the general facts and rules which have relation to the present case, there should at this time occur a subsidence of the true fever-process. The marked characteristic of the enteric poison is the lighting up of a febrile action, which is marked by an elevation of temperature, and which pursues a certain undulating course distinguished by great regularity. The changes of temperature from morning to evening, from week to week, are regulated by a law so commonly observed, that these changes afford an element of certainty in the diagnosis not only of the character of the fever, in the first instance, but of its greater or less severity, its progress from day to day, and the extent to which the local lesions are producing a constitutional impression. The fever-process, during the first three weeks and part at least of the fourth, had pursued a course so regular, and though severe, yet so free from complication, that when it became our duty, on Thursday evening last, to review the course of the disease up to that date, and to draw from the past, and from a discussion of the status at the moment of writing, deductions for anticipating the future, we felt authorised to augur favourably from the fact that only a few days remained during which the fever-process should normally continue, and that after the expiration of those days we might anticipate a restoration to normal temperature and a commencement of convalescence. Before this, it might well have been expected that, except for the fear of relapse during convalescence, the Prince would enter upon a course of uninterrupted convalescence.

The symptoms which appeared on the following day, and which rudely banished these smiling prospects, were developed with great suddenness, and were accompanied by incidents exciting immediate alarm, inasmuch as they gave rise to especial perils, which might at any moment have terminated life by their incidental effects. They have been followed by a rare combina-

tion of symptoms, which have greatly complicated the vital questions at issue. There was, first, an alarming irritation of the bronchi, with an excess of secretion, which was the more distressing that there was little power to clear the air-passages by voluntary or involuntary effort and to expel it. Thus, this suffocative catarrh led to the most severe symptoms of dyspnoea. It was accompanied by extreme irritability of the bronchial mucous membrane, and alarming reflex spasm. There was also great nervous prostration. As these symptoms continued, the alarm which they must necessarily cause increased; and the situation on Friday night and during part of Saturday was desperate: there were alternations of ease and of suffering, due to the supervention or cessation of suffocative dyspnoea. Twice these attacks recurred in their most intense power during the night. It is not our part, in discussing the scientific and clinical facts of this sad illness, to dwell on the pain which such scenes inflict on those nearest and dearest to the patient. But it may not be out of place to suggest, as a topic of consolation, that in truth these attacks involve less acute suffering to the patient than the struggles to which they give rise. By the merciful operation of physiological laws, asphyxiating spasm does, by the very intensity of its action, suspend in a great measure nervous sensibility and the perception of pain. Such struggles are suggestive of agony, and that phrase is often employed, but it represents the objective suggestions which they impress upon the mind of the beholder much more than the subjective sensations of which the pain of the sufferer takes conscious notice. A little reflection, indeed, will remind even the unlearned how much the struggling associated with obstructed respiration is automatic and unconscious. Nothing, for example, is more distressing to behold, or more suggestive of agony, than the struggles of the drowning man, in whom death is produced by suffocative asphyxia by a mechanism physiologically not dissimilar from that of suffocative catarrh; but it is familiarly known that there is none of the pain which the struggle seems to imply, but that, on the contrary, in death by drowning the sensations are far from being those of extreme distress. Those who have been snatched from the jaws of death, after periods of long suspended animation, have even been known to declare that their sensations have been far from disagreeable. They have indeed, as in all cases of suffocative asphyxia, passed through the condition of anæsthesia from accumulation of carbonic acid gas in the blood, which does not differ much from that of anæsthesia artificially produced by nitrous oxide and other agents.

Returning from this, we trust pardonable, digression, we may point out that there are certain clinical questions of great practical importance in connection with this symptom of suffocative catarrh. In the first place, it will remind us of the fact, that the best observers have noted as a pathological fact that, although the ulcerative action on the mucous membrane which characterises the evolution of the enteric poison is manifested distinctively in the glands of the small intestine, and even by preference in the glands of a particular part of the small intestine, yet the tendency to ulcerative action is not confined to those glands, but shews itself in different parts of the system. Thus, the bronchial glands have been observed, by Chomel and Louis, to be occasionally involved. The question then would arise, whether there was bronchial ulceration in the present case. The severe irritation occasioned by the accumulation of the bronchial secretion, and the occasional violent reflex spasm produced by efforts to clear the lung, might favour

such belief. But where there is ulceration, of course the sputum would, under particular circumstances, and at intervals, afford indications of the breach of surface. It is extremely satisfactory to know that there have been no such indications; and, so far as can be at present determined, the condition is one which is accurately described by speaking of it in the terms which we have already used. It is equally satisfactory in such a case to know that there are no physical indications of pneumonia, or of any organic affection of the lung-tissue.

Passing now to another series of conditions which, in judging of such illness, it is necessary to consider as of primary importance, we must pause for a minute to weigh the inferences derivable in any cause from the information afforded by the official bulletins, that there was, at the close of last week, a sudden elevation in temperature, which is, of course, in typhoid, the strict interpretation of the words properly employed in the bulletin to express the clinical fact. This rise in temperature at the period of the fever when it occurred, presents problems the more important that it is usually indicative of grave local complications, such as severe enteric ulceration or affections of the tissue of the lung, etc., which are here happily understood not to be present. In the absence of these, the rise in temperature presents difficulties which require caution in solution. Its persistence is a circumstance which somewhat enlightens the question. In the first place, it will be remembered that the date of commencement of the true fever-process has been assigned to November 13th, on that somewhat uncertain kind of evidence which in such cases is alone available. But the onset of this kind of fever is proverbially insidious, its incubation slow, and its prodromata variable. It is then possible, in this as in every case, that the actual day of commencement of the fever was somewhat antedated; and, let it be observed that physicians, ever seeking to lighten the anxieties and shorten the fears of their patients, are always unconsciously urged by their impulses to date the commencement of typhoid, when summoned to its developed stage and required to fix the date, at the earliest probable day; for this affords the hope that its termination will be the sooner at hand. This difficulty in absolute precision, and even the unconscious mental bias in favour of a leaning to the earliest of probable dates, might have led to the antedating in the Prince's case. In that case, the process would have been prolonged a day or two longer than calculated by all of us. As we watch the reports of its progress with an intensity of anxiety, heightened by every consideration of loyalty and affection, a few days more might yet see the reduction of temperature to a normal standard, a subsidence of fever, and the commencement of convalescence.

Since the above remarks were written, we learn by telegraph from an authentic source, that the turn which the symptoms have taken since Wednesday night and in the course of Thursday, authorises the belief that the exacerbation which took place on Thursday of last week was not the commencement of a new cycle of fever, but a recrudescence, which is now about to decline. The state of the Royal patient's temperature, pulse, and general condition, all afford most favourable indications. We need not say with how deep satisfaction we publish this glad news, derived, as we have already said, from a trustworthy source. We are happy to learn that the boy Blegg, who had been seriously ill in the latter part of last and beginning of the present week, is much improved; and that on Thursday morning Dr. Lowe pronounced him to be going on well. Her Majesty and

the Princess Louise graciously visited the patient on Thursday morning.

Let us only add, that it is known that from first to last the physicians in attendance upon the Prince have been in complete accord in principles and details of treatment, and in the interpretation of symptoms. They would, indeed, have failed to respond to the highest motives of duty and strongest promptings of feeling, if they had not shewn the most complete and untiring devotion. They have not failed; and in their untiring and protracted exertions they have been throughout supported by the gracious confidence and kindness of the royal relatives of the Prince.

#### THE SANITARY STATE OF SCARBOROUGH.

WE hope that the important statements which have appeared in the pages of the JOURNAL, and in those of our contemporaries, regarding the sanitary condition of Scarborough, will receive the immediate attention which they undoubtedly demand. The outbreak of typhoid fever amongst the members of the royal party naturally at first led to the investigation of the sanitary condition of Londesborough Lodge—a task of considerable difficulty and delicacy, but which has been faithfully carried out by our Commissioner, with what results we last week intimated. Exception has been taken by Mr. Dale and others in the daily papers to some of the statements in our report; but the conditions rendering Londesborough Lodge liable to sewage-infection, nevertheless existed, although, perhaps, in a somewhat less degree than we were at first led to believe. This, together with the fact that several members of the party coming from different parts of the country were struck down by typhoid fever at dates corresponding to the natural term of incubation of the fever, are facts which it is difficult otherwise to account for, than that this disease was contracted at Scarborough. The analyses of the various waters at Londesborough Lodge, which are given in detail elsewhere, fail to account for the outbreak. The results, by means of the zymotic test, of the examination of the Bristol and Scarborough waters by Dr. Ferrier, indicate that they are both of the highest degree of purity, and free from the organisms which he says are continually found in sewage and putrid matter, and in water directly contaminated with such. Dr. Ferrier states—so far as the zymotic test has been elaborated—that there is no likelihood of either of these waters having been the agent in carrying typhoid contagion: and the chemical examination so far bears out his conclusions.

It appears that the pump-water from the kitchen or scullery at the Lodge contains a decidedly larger amount of free ammonia than is commonly met with in good water; and, although this affords reason for suspecting sewage-contamination, it may possibly be due to other causes. On the other hand, this water, we were informed, was used only for washing purposes, and could not by any means have been in any way employed for cooking.

But although it is clear that the condition of Londesborough Lodge was amply sufficient to account for the outbreak of fever, the sanitary condition of Scarborough itself, in the centre of which the Lodge is situated, has, fortunately for the inhabitants, as it happens, become the subject of comment and investigation. We have received a large amount of reliable evidence to show that it is in a most unsatisfactory condition; and, from personal inspection, we are enabled to bear out many of the statements made to us. A great part of the town is altogether undrained—the system of cesspits and privies, and the supply of water in some localities, being such as to lead to the extensive prevalence of zymotic diseases. It is true that this state of matters is chiefly limited to the northern or older part of the town; but the southern portion is by no means altogether free from charges of insanitation.

In a health-resort like Scarborough, it could have been expected that

an efficient system of inspection by a duly qualified medical officer would have been in force; but this, it appears, is not the case. There is no medical officer of health, Dr. Taylor acting for the Local Board merely in reference to infected vessels arriving at the port, and the inspection of diseased meat.

The authorities of Scarborough appear to be anxious to deny the sanitary defects of their town, while many of the leading medical men are satisfied that nothing short of a government investigation will secure efficient sanitary measures for Scarborough. Such an investigation, we earnestly hope, will be made, which will embrace an inquiry not only into the whole circumstances of the outbreak of typhoid fever amongst the members of the royal party, but into the general sanitary condition of the town of Scarborough.

#### THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

THE following bulletins have been issued during the week up to the time of our going to press, by Sir William Jenner, Dr. Gull, and Dr. Lowe, the physicians in attendance on His Royal Highness the Prince of Wales at Sandringham.

Dec. 7, 9 A.M.—His Royal Highness the Prince of Wales has passed a quiet night. The decline of the symptoms continues regularly.

Dec. 7, 5 P.M.—His Royal Highness the Prince of Wales has passed a quiet day. There is no material change in the symptoms.

Dec. 8, 8 A.M.—His Royal Highness the Prince of Wales has passed a very quiet night. There is a considerable increase in the febrile symptoms.

Dec. 8, 1 P.M.—His Royal Highness the Prince of Wales has slept at intervals during the morning; but there is no abatement of the graver symptoms.

Dec. 8, 5.30 P.M.—His Royal Highness the Prince of Wales continues in a precarious state. The exacerbation of the symptoms, which began late last evening, has been attended by great prostration of the strength.

Dec. 8, 9.30 P.M.—His Royal Highness the Prince of Wales has slept, but still continues in a prostrate condition.

Dec. 9, 1 A.M.—His Royal Highness the Prince of Wales continues in the same condition as at 9.30 P.M.

Dec. 9, 8 A.M.—His Royal Highness the Prince of Wales has slept; the exhaustion has not increased, and the general conditions are somewhat more favourable.

Dec. 9, 12.15 P.M.—His Royal Highness the Prince of Wales has passed the morning more tranquilly. The febrile paroxysm of yesterday is subsiding; there is no increase of exhaustion.

Dec. 9, 5 P.M.—His Royal Highness the Prince of Wales has passed the afternoon quietly; but there has been no change in the symptoms since noon.

Dec. 9, 10 P.M.—His Royal Highness the Prince of Wales has slept at intervals during the evening. There is no improvement in the symptoms since noon.

Dec. 10, 1 A.M.—His Royal Highness the Prince of Wales has had some sleep since ten o'clock. The symptoms continue unchanged.

Dec. 10, 8 A.M.—His Royal Highness the Prince of Wales has passed a quiet night. Although there is still great prostration, the graver symptoms have not increased.

Dec. 10, Noon.—His Royal Highness the Prince of Wales has passed the morning tranquilly; the general condition is somewhat more satisfactory than yesterday.

Dec. 10, 5.30 P.M.—His Royal Highness the Prince of Wales has passed an unquiet afternoon, with a return of the more urgent symptoms.

Dec. 10, 10.30 P.M.—His Royal Highness the Prince of Wales has been restless during the evening, and there is no abatement of the urgent symptoms.

Dec. 11, 1.30 A.M.—His Royal Highness the Prince of Wales has had a little sleep. The symptoms are unchanged.

Dec. 11, 8.15 A.M.—His Royal Highness the Prince of Wales has passed a restless night, with a further recurrence of the graver symptoms; the state continues precarious.

Dec. 11, Noon.—His Royal Highness the Prince of Wales remains in the same precarious condition. There has been no alteration of the symptoms during the morning.

Dec. 11, 5 P.M.—His Royal Highness the Prince of Wales has passed a very restless afternoon; but the exhaustion does not increase.

Dec. 11, 10 P.M.—His Royal Highness the Prince of Wales has not slept during the evening, but the general state continues unchanged.

Dec. 12, 1.30 P.M.—His Royal Highness the Prince of Wales is passing a very restless night, without signs of improvement.

Dec. 12, 8 A.M.—His Royal Highness the Prince of Wales has passed a very restless night. Though there are no signs of improvement, exhaustion has not increased.

Dec. 12, 12.30 P.M.—His Royal Highness the Prince of Wales has passed a restless morning. In all respects the general condition continues unchanged.

Dec. 12, 5 P.M.—His Royal Highness the Prince of Wales has passed a somewhat less restless afternoon. The general condition remains unchanged.

Dec. 12, 10 P.M.—His Royal Highness the Prince of Wales has passed an quiet evening, but the prostration does not increase.

Dec. 13, 1 A.M.—His Royal Highness the Prince of Wales's condition is unchanged.

Dec. 13, 8 A.M.—His Royal Highness the Prince of Wales has passed another very restless night. The conditions do not improve.

Dec. 13, Noon.—His Royal Highness the Prince of Wales has passed the morning without change of symptoms.

Dec. 13, 5 P.M.—His Royal Highness the Prince of Wales has passed a very unquiet afternoon. There is no abatement of the gravity of the symptoms.

Dec. 13, 10 P.M.—His Royal Highness the Prince of Wales has passed a less unquiet evening.

Dec. 14, 1 A.M.—His Royal Highness the Prince of Wales continues to be less restless.

Dec. 14, 8 A.M.—His Royal Highness the Prince of Wales has slept quietly at intervals during the night; there is some abatement of the gravity of the symptoms.

Dec. 14, Noon.—His Royal Highness the Prince of Wales has passed a tranquil morning. The gain during the night is maintained.

Dec. 14, 5 P.M.—His Royal Highness the Prince of Wales has passed a quiet afternoon. There is no change of symptoms since the morning.

A COMMISSION has been appointed by the Portuguese Government for the purpose of framing a pharmacopoeia for the kingdom.

MR. J. HORNIMAN has presented a donation of £1,000 towards the building fund of the Croydon General Hospital.

AN Italian translation of Dr. Tilt's *Change of Life*, from the pen of Dr. Eugene Rey, will shortly appear at Rome.

THE question whether it was advisable to have a fixed tariff of medical fees, either general or local, was discussed at the recent meeting of the Italian Medical Association. The decision was, by a not very remarkable majority, in the negative in both cases.

AT a meeting of the Northampton Town Council on December 4th, a testimonial from the Royal Humane Society was presented by the Mayor to Mr. J. M. Bryan, jun., a son of our respected associate, Dr. Bryan, on account of the humanity and courage which he had displayed in saving the life of a lad named Thomas Kirk, who had fallen into the canal.

THE Italian Anthropological and Ethnological Society commenced its session on November 23rd. Professor Mantegazza read a letter from Mr. Darwin on sexual selection, and pointed out several objections to the theory of the English naturalist. The improvement in the means of forming an Italian ethnological collection was commented on at the meeting.

A MEETING of the Association of Medical officers of Health will be held at the Scottish Corporation Hall, Crane Court, Fleet Street, to-day (Saturday, December 16th), at 7.30 P.M. The Report of the General Purposes Committee will be read; and Mr. W. H. Michael, Barrister-at-Law, will deliver an address on Future Sanitary Legislation.

#### TOO MANY GESE.

WE have received a letter from a correspondent at Southampton complaining of a nuisance which, although of a novel character, is highly injurious, and as such calls for an appeal against a recent decision of

the Hants county justices. It appears that a French dealer has for some time past been in the habit of supplying the ocean steamers with geese; and, in order to meet the demand, he keeps at least a thousand geese at one time in a very limited area, and in the heart of a large and populous town. This, especially during the hot weather, caused an intolerable nuisance, which was considered of a nature so injurious to the health of the inhabitants as to necessitate the interference of the local inspector of nuisances. That official accordingly applied for, and obtained, a summons against the proprietor of the geese. The summons was, however, dismissed, in consequence of the imperfect description given of the nuisance complained of. A second summons was subsequently obtained, upon the ground of the "incessant noise of the geese day and night, coupled with the injurious effect on the public health". It was argued in support of the summons that, apart from the noxious effluvia, the incessant gabbling of the geese day and night was prejudicial to the health of those whose slumbers it disturbed. Medical testimony was given to this effect; but the justices for the second time declined to adjudicate in the matter, upon the ground "that the geese did not come within the meaning of the Nuisance Removal Act". In delivering their decision they said: "We cannot seriously discuss the question of a goose's proper place in the scale of creation. We have been accustomed to consider the goose as belonging to the animal kingdom, and must, therefore, be content to deal only with the positive words of the Act." As the bench admit that the goose is an animal, and the eighth section of the Act (as interpreted by the General Board of Health) provides that "any animal so kept as to be a nuisance or injurious to health may be removed", we confess ourselves at a loss to understand why the justices hesitate to remove the nuisance.

#### TESTIMONIAL TO AN ITALIAN DISTRICT PHYSICIAN.

THE municipality of Castiglion d'Orcia has presented Dr. Comparini, district medical officer of Campiglia, medical works to the value of 140 lire (£5 : 12), in recognition of the zeal and devotion with which he has performed his duties. *L'Imparziale* regards this as a rare instance of public generosity, and hopes that the example may be frequently followed.

#### PRESENTATION OF A MEDAL TO SKODA.

On the 7th instant, a deputation of the "Doktoren-Collegium" in Vienna, headed by Dr. Chrastina, Dean of the Faculty of Medicine, visited Dr. Skoda at his residence, and presented him with a medal in commemoration of the ovation which he received on his retirement from professorial duties some time ago. Dr. Chrastina, who wore his robes of office as Dean, delivered an address to Dr. Skoda, concluding with the expression of the hope of himself and his colleagues that Dr. Skoda would long enjoy in health his *otium cum dignitate*. Dr. Skoda, who was evidently much moved, desired the deputation to convey to the college the expression of his gratitude and good feeling.

#### ALLEGED ASSUMPTION OF A MEDICAL DEGREE.

AT the Shrewsbury County Court on the 4th instant, Thomas Andrews sued F. H. Davies for the sum of £4 : 13 : 6. The bill was made out as follows: "Mr. Frank Harry Davies to Thomas Andrews, M.D. To professional attendance, medicine, etc." The plaintiff stated that he was only a chemist and druggist when the medicine was supplied, and he had charged accordingly: he had since that time passed as a doctor of medicine. In cross-examination, he said that his diploma was a foreign one, obtained from America. He further said that he had two diplomas; but did not state the source of the second. After a persistent endeavour on the part of Andrews's solicitor to have the case settled irrespectively of the question of the medical qualification, the summons was withdrawn on the suggestion of the judge, the plaintiff paying the costs. The Honorary Secretary of the Shropshire Ethical Branch has issued a summons to the members of the Council, to meet in order to consider if any and what steps should be taken to vindicate the honour of the profession in the matter.

## DEATH OF M. PAUL DUBOIS.

M. PAUL DUBOIS, formerly Clinical Professor of Midwifery in Paris, and one of the most eminent obstetric authorities in France, died on November 29th, at the age of 76, after a long illness, which had obliged him ten years ago to retire from practice. He was the son of Antoine Dubois, Professor of Midwifery and Chief Surgeon of the Maternité. In 1820, his father had him appointed assistant-surgeon, and gave him the full benefit of the large experience which he had accumulated; and, in 1825, resigned his office to his son. In 1834, the Chair of Clinical Midwifery in the Faculty of Medicine being vacant, a *concours* for a professor took place, in which M. Paul Dubois was successful. He held the professorship twenty-five years. He was the author of numerous highly valuable essays on various obstetric subjects, and did much for the advancement of midwifery, on which subject he is justly regarded as one of the highest authorities.

## AN ARTESIAN WELL.

AN Artesian well has been sunk in the courtyard of the naval hospital at Rochefort to a depth of 846 mètres (2774 feet). M. Roux, pharmacien of the hospital, reports that the temperature is 41 deg. cent. (about 105 Fahr.) Contrary to what is generally observed in artesian wells, the water contains a large quantity of saline matter—sulphates of sodium and lime, chloride of sodium, iron, manganese, etc. When taken from the well, it is clear, but becomes turbid on exposure to the air, and leaves an ochrey deposit. It is quite unfit for drinking or washing. During the process of boring the well, the instrument used became magnetised; its several portions each forming a magnet with austral and boreal poles, and capable of rendering iron magnetic.

## THE HOSPITAL OF ST. JOSEPH IN LISBON

IN an article in the *Correio Medico de Lisboa*, the hospital of S. José in Lisbon is described as having been originally a convent, which, notwithstanding the attempts made for its improvement, it has not yet been possible to render fitted for the purpose to which it is now applied. It is situated at the extremity of the most populous and most unhealthy quarter of the city, and contains 800 beds. In the same neighbourhood are the other civil hospitals; viz., St. Lazaro with 60 beds, Santé Anna with 66, the Desterro Hospital with 200, the Rilhafoles Asylum with 500 insane patients, and a pauper asylum with more than 700 inmates; together with a hospital for children, as yet only half built. In the hospital of S. José, some of the wards open into corridors, but others are so closely connected that the emanations are diffused from one into the other. Hence cases of diarrhoea are frequent; and in some of the surgical wards, at certain times of the year, the most trivial incision is liable to be followed by fatal suppurative or erysipelas; pyæmia figures notably among the causes of death after the more severe operations. In the five years 1866-1870, the number of medical cases was 25,787, with a mortality of 5,341, or 20.7 per cent; of surgical cases, 17,553, with 1,273 deaths, or 7.2 per cent.

## VARIATIONS IN THE DIAMETER OF ARTERIES.

DR. BENECKE of Marburg has since 1868 carried on a series of observations with the object of ascertaining the variations in the diameter of the arteries in different diseases. The idea which he holds may be thus expressed. Regarding the etiology of various diseases, hypotheses alone exist; and it is only by assuming the existence of pre-disposition, that we can at present explain why the same morbid influence should in one person produce pneumonia, in another articular rheumatism, etc. Dr. Benecke believes that the disposition to special forms of disease is to be sought for in some structural peculiarities of the organism, and has set himself to inquire whether there are not variations in the diameter of the arteries which might throw light on the subject. He has examined, in patients dying in the hospital, the diameters of the ascending aorta a centimeter above the valve; of the thoracic aorta twelve centimeters beyond the angle of the left subclavian artery; of the abdominal aorta one or two centimeters above its

termination; of the pulmonary artery a centimeter above the valves. In the bodies of persons 100 centimeters in height, he found the following variations. 1. Ascending aorta: maximum, 54 millimeters; minimum, 32.4 millimeters; difference, 21.6 millimeters. 2. Thoracic aorta: maximum, 36 millimeters; minimum, 23.1 millimeters; difference, 13.1 millimeters. 3. Abdominal aorta: maximum, 26.3 millimeters; minimum, 14.7 millimeters; difference, 11.6 millimeters. 4. Pulmonary artery: maximum, 51.2 millimeters; minimum, 31.3 millimeters; difference, 19.9 millimeters. Age has some influence on the variation; sex very little, if any. The smallest measurements were found in four cases of scrofula and two of chronic brain-disease.

## INTEMPERANCE AND THE TREATMENT OF DISEASE BY ALCOHOL.

A CIRCULAR has been issued by Dr. Burrows, President of the Royal College of Physicians, to a number of the leading medical men, calling attention to the tendency to intemperance engendered by the use of alcohol in disease, and asking for their support in guarding against this danger. The object is one likely to gain the sympathy of thoughtful practitioners. It will in due course be published, with the signatures attached, in the medical journals.

## THE NORTHAMPTON GUARDIANS AND VACCINATION.

AT the meeting of the guardians of the Northampton Union on the 5th instant, a long discussion on vaccination took place. Dr. Stevens, Inspector of the Local Government Board, was present, and addressed the guardians on the means to be taken in consequence of the threatening aspect of the epidemic of small-pox. He stated that he had found that, of 1933 children born during the year ending September 30th, not 600 had been vaccinated. In the district of St. Giles's, there had been 31 deaths this year from small-pox, 23 of which had occurred in October and November. Most of the deaths had occurred in persons under 14 years of age; and in only one vaccinated individual had the disease proved fatal. In the subdistrict of All Saints, there had been four deaths—one only of them on a vaccinated infant. He plainly told the guardians that he thought "that the state of things was really a scandal." He urged the guardians to appoint at once persons to make a house-to-house visitation, beginning in localities where small-pox was pressing, issuing placards with a clear statement of what was required, showing that adults could be vaccinated or re-vaccinated gratis, and setting forth generally the law on the subject. A long discussion followed, and ultimately it was resolved, by a majority of nine against seven, to "send notices to all parents of children born between January 1871 and July 1872, and who appear from the registrar's returns to be unvaccinated"; and to "take compulsory measures against all such parents unless their children be vaccinated forthwith after the delivery of the notices." The suggestion to establish a house-to-house visitation was therefore not carried out; and, although the measure taken by the guardians is, so far as it goes, a good one, they have overlooked the necessity of providing for the vaccination of children above the age of infancy, notwithstanding that Dr. Stevens clearly pointed out to them that no fewer than fifteen of the deaths had occurred in individuals between 4 and 14 years of age.

## THE COLLEGE OF SURGEONS AND MR. WASHINGTON EVANS.

IT will be in the recollection of the readers of the BRITISH MEDICAL JOURNAL that several months ago the attention of the authorities of the Royal College of Surgeons was called by us to the unprofessional pamphlets of Mr. George Washington Evans, of Reading, a member of that College. At the time, little was done in the matter, and the pamphlets were distributed widely, until professional and general feeling was so strongly expressed, that action was taken by the Council of the College, who appointed a committee to investigate and report. Sir James Paget, Bart., as chairman, submitted the following report at a meeting of the Council on the 14th inst.

"Your Committee—appointed on the 8th of June last, to consider and report to the Council upon the letter of the 4th of May last, from

Mr. J. P. Wilton, Honorary Secretary to the Gloucestershire Medical and Surgical Association, and the previous correspondence in relation to the pamphlets issued by Mr. George Washington Evans, of Reading, a Member of the College—have taken the subject into consideration at two meetings, viz., on the 5th of July last and on this date, and have agreed to the following Report; viz., That in the opinion of your Committee the pamphlets issued by Mr. George Washington Evans are, in the words of Clause 2, Section XVII, of the Bye-laws, 'prejudicial to the interest' and 'derogatory to the honour of the College', and 'disgraceful to the profession of surgery.' And that your Committee accordingly recommend that notice should be given to Mr. Evans that such is the opinion of the Council; and that if there be any further distribution of these or similar pamphlets, the Council will proceed to deal with him under Section XVII of the Bye-laws."

The Secretary was directed to furnish Mr. Wilton with a copy of the proceedings, and to acquaint Mr. Evans with the decision of the Council on his conduct, as above expressed.

#### ST. MARY'S HOSPITAL: PRESENTATION TO DR. SIBSON AND MR. LANE.

ON Wednesday, the 13th instant, a large number of the past and present students of St. Mary's Hospital met in the board-room to present a piece of plate to Dr. Sibson, and a handsome timepiece to Mr. Lane, on their retirement from the respective offices of physician and surgeon, after twenty years of valuable service in the school and hospital. The presentation was made, on behalf of the students, by Mr. Gascoyen, whose observations, together with the replies of Dr. Sibson and Mr. Lane, were received with warm demonstrations from the large number of students whom the occasion had brought together.

#### MR. EDWARD COCK.

AT a meeting of the Council of the Royal College of Surgeons on Thursday last, a letter from Mr. Cock was read, resigning his seat as a member of the Court of Examiners, to which he was elected in 1867, and requesting that he might not be nominated for re-election. Mr. Cock will be remembered and respected as a generous and impartial examiner. He will continue his connexion with the College as a member of the Dental Board.

#### SMALL-POX.

THIS disease has prevailed in the town of Gotha to such an extent that, in a population of 20,000, twenty-five cases have occurred daily, with a high percentage of mortality. The Government of Saxe Gotha, after consultation with the medical and magisterial authorities, has ordered a general vaccination of the inhabitants. For this purpose, the town has been divided into districts, each house of which has been visited by a medical man, accompanied by a police officer. More than three hundred persons have already died of small-pox there within the last few months.

#### INFLUENCE OF LIGHT ON CANE-SUGAR.

M. RAOULT has informed the Academy of Sciences, as the result of some researches which he has made, that cane-sugar becomes transformed into grape-sugar under the prolonged influence of light. Having dissolved 10 grammes of white sugar in 50 grammes of pure water, and boiled the solution for a few minutes, he placed equal portions in two white glass tubes, which were then hermetically closed. One was deposited in a dark place, while the other was exposed to light. Five months afterwards, the tubes were opened, and the contents of that which had been exposed to light gave the reaction of glucose.

### SCOTLAND.

Dr. JOHN G. M'LENDRICK delivered an excellent lecture on "The Growth and Nutrition of the Human Body," on the 7th instant, to a large attendance in the Museum of Science and Art, Edinburgh.

DR. ANGUS FRASER has been appointed Physician to the Aberdeen Infirmary, to succeed Dr. Harvey, resigned.

IT is stated in the *Scotsman* that twenty-eight ladies have matriculated at the University of Edinburgh, and that ten of them are students of medicine.

#### THE PROPOSED CONVALESCENT HOSPITAL FOR DUNDEE.

THE *Dundee Advertiser* states that Miss M. A. Baxter, of Balcavies, Ellangowan, has expressed a wish to be associated with her brother, Sir David Baxter, Bart., in the erection of the convalescent hospital for Dundee, and has offered to contribute £5,000 towards the building and its endowment. Attention is being directed to sites near the Balgay Hill and the Baxter Park as suitable for such an hospital.

#### GLASGOW LYING-IN HOSPITAL.

THE following gentlemen have been elected medical officers for the ensuing year, viz.:—*Consulting-Surgeon*—Dr. George Buchanan, Professor of Anatomy in Anderson's University; *Physicians-Accoucheur*—Dr. J. G. Wilson, Professor of Midwifery in Anderson's University, and Dr. R. D. Tannahill.

### IRELAND.

THE Dublin Hospital for Incurables is suffering from lack of funds. Last board day ten patients were admitted, and the month's contributions amounted to the munificent sum of £12 : 5.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

AT an adjourned general meeting of the Society, held on Saturday, December 9th, 1871, the following were elected office-bearers for the present session. *President*: Jolliffe Tufnell. *Vice-Presidents*: Thomas Beatty, Samuel Gordon, Edward Hamilton, Henry Kennedy, John Thomas Banks, and John Denham. *Council*: Robert Adams, Sir Dominic J. Corrigan, John Hamilton, Thomas Hayden, James S. Hughes, George Kidd, Robert Law, Benjamin G. M'Dowel, Robert M'Donnell, William Moore, George H. Porter, and James H. Wharton. *Honorary Secretary*: William Stokes. *Secretary and Treasurer*: Robert W. Smith. *Secretary for Foreign Correspondence*: Robert D. Lyons.

#### THE STREETS OF DUBLIN.

STREET-cleansing seems to be a science to the rudiments of which the Corporation of Dublin are only just awakening. As in most things Irish, there seems no half-heartedness in Dublin street-dirt. A local paper says: "Things are as bad in the most fashionable street as in the most backward slum. Everywhere it is sludge and mud, an all-pervading nastiness, which smears and smells and sticks, and can not be avoided, strive how you will. A handful of scavengers, with scrapers and brooms, face the slimy stream—so many Partingtons contending with the ocean." A committee of the Corporation has taken the matter up, and at a meeting this week decided on "prompt and energetic measures." Better late than never; and it is to be hoped that the committee will not relax its efforts till the Augean stable of "dirty Dublin" has been cleansed.

#### FEVER IN THE COUNTY GALWAY.

FEVER is raging badly in the district of Carrabrowne, county Galway, there being fifteen cases in one small village. The sanitary condition seems very wretched, and great apprehensions exist in the town of Galway, from its filthy state, of the results should the fever gain head there. The chairman of the Galway Union, at a recent meeting, combatted any special efforts in the direction of increased cleanliness by the argument that, as fever was often brought on by fear, he thought they should not become frightened. Nobody gave vent to the comment, that fever was considerably oftener produced through filth.

## OUT-DOOR HOSPITAL RELIEF.

A CONFERENCE was held on Tuesday last at the house of the Society of Arts, John Street, Adelphi, under the auspices of the Council of the Charity Organisation Society, "on the best methods of checking the abuses now incidental to out-patient relief, with special reference to the expediency of extending the provident principle." The object of the conference was to discuss the province of the Poor-law, the dispensary, and the hospital, with reference to the sick poor, and to promote concerted and harmonious action among these agencies.

The chair was occupied by Mr. W. H. SMITH, M.P.; and there were present The Right Hon. James Stansfeld, M.P. (President of the new Board of Control), Sir Charles Trevelyan, Mr. Fairlie Clarke, Dr. Guy, Dr. Ford Anderson, Dr. Macfarlane, Dr. Mackenzie, Dr. Aldis, Colonel Fremantle, Mr. Samuel Gurney, Mr. Gurney Hoare, Mr. Charles Hoare, Hon. W. W. Vernon, Lord J. Percy, Rev. Harry Jones, Hon. A. Kinnaid, M.P., Rev. J. F. Kitto, Mr. E. Enfield, Mr. E. W. Holland, Mr. A. H. Hill, Mr. C. F. d'A. Orred, Mr. T. F. Buxton, Mr. G. Cowell, Rev. Harvey Brooks, Mr. T. E. Platten, and Mr. T. Holmes.

Mr. W. H. SMITH, M.P., said the Committee considered that it would have been expedient on some grounds that the discussion should have been postponed, but it was felt that the subject was not one which it was undesirable to consider at a period when men's hearts were filled with sorrow, and when they were, perhaps, more ready to give consideration to those means which should be made use of to alleviate sickness and disease in others than they would be at a period of general and entire prosperity. In 1854, Dr. Guy read a paper in the Statistical Society, in which he drew attention to the magnitude of the work which was going on in connexion with the London hospitals, and to the want of regulation, of system, and of organisation in the administration of charity at the hospitals. Nothing, however, had been done; and it was now felt that some system should be devised by which the wants of those who were sick and suffering should be relieved, while the largely pauperising element mixed up with the present arrangements should be, if possible, removed. Practically, the out-patient wards of the hospitals were open to all comers. No matter how many patients sought relief; no matter whether the sickness was severe or light; no matter whether the means of the applicants were large or small, they appealed to the physician or surgeon, and they were seen in their turn. It was impossible to deny that there were great evils mixed up with this work of charity. Very many persons were brought together, some suffering under severe illness, some slightly indisposed, some suffering from that imaginary malady which many of us were afflicted with from time to time, and which required a little fresh air and exercise. But there could be no question whatever that one great evil existed—that acute sickness was brought into contact with persons who were predisposed to acquire sickness, and that the seeds of disease were spread from the out-wards all over the metropolis. There was another evil existing which was also a very serious one—namely, the absence of check and control of the patients, so as to distinguish between persons who possessed means and who ought to make provision against the time of sickness, and those who were really objects of charity. That state of things was a distinct invitation to pauperism, and injuriously affected the persons who sought relief, and who ought not to obtain it gratuitously. On the other side of the picture, it was impossible not to admit that the position of a person of limited means in London or in the great centres of industry in time of sickness was a sad one, and full of difficulty. He had himself had much experience of the great difficulties with which the most respectable and independent of the working classes of London had to contend in being called upon to pay bills for medical attendance, amounting to £5, £10, and in some cases to £30. It was impossible not to feel that it was very hard for those who earned 30s. or £2 a week to pay such bills. Some system, some organisation or arrangement, was therefore necessary under which an independent working-man in this metropolis or in any part of the country could find for himself and his family, at his own proper cost, without loss of independence or self-respect, provision for the day of sickness. He would not indicate the way in which that provision should be made; but he could not help pointing out that, on the one hand, there did exist a vast amount of evil and danger to health from the present system, and that, on the other hand, there did not exist means by which the working-man—the individual who was not a pauper, but who was not in receipt of a considerable income—could make provision for his necessities in time of sickness. There was no machinery now in existence whereby such provision was made consistently with the self-respect and health of the individual and his family, and the question was one of wide interest and importance to the future welfare of the country.

Letters expressing regret for inability to attend were received from the Earl of Lichfield, the Earl of Derby, the Bishop of London, Sir W. Fergusson, Sir J. Paget, Mr. Corrance, etc.

Mr. FAIRLIE CLARKE, Honorary Secretary of the Medical Committee of the Charity Organisation Society, then read a paper in which it was stated that last year the out-patients at 15 general hospitals were 590,151, at 34 general dispensaries 305,491, at 39 special hospitals and dispensaries 261,374; making a total of 1,157,016, or more than one-fourth of the whole inhabitants of London receiving gratuitous medicine and attendance at the metropolitan hospitals and dispensaries. In addition there were 17 hospitals and dispensaries which made no return, and of those which were assisted by the medical service of the Poor-law. Surely it could not be necessary that one in four of the inhabitants of London should depend upon public charity for medicine and attendance. No doubt a large portion of these persons were well able to pay a private practitioner, and the remainder could surely pay the six or eight shillings a year which was called for by the provident dispensary. The provident principle had already been tried in the metropolis, but had languished in consequence of the competition of the free charities. In the provinces, on the contrary, they had worked well, especially in the manufacturing districts. In Derby there were two, one with 4,000, the other with 1,100 members; so that 1 in 7 were enrolled in provident dispensaries. The same proportions would give in London 450,000 persons enrolled in provident dispensaries, whereas, as a matter of fact, there were only 25,000. The Charity Organisation Society suggested that the existing free dispensaries should at once be converted into provident dispensaries, and be affiliated with the hospitals of the district, so that the members of the provident societies should be eligible when necessary for admission to the hospitals.

Sir C. TREVELYAN moved—"That this conference is of opinion that there exists a great and increasing abuse of the out-door relief at the various hospitals and dispensaries of the metropolis which urgently requires a remedy."—Dr. MEADOWS seconded the resolution, which was adopted after a discussion, in which Mr. Pownall, Dr. Rogers, Dr. Guy, Mr. Holland, Dr. Aldis, and Mr. Kinnaid, M.P., took part.

Dr. ACLAND moved—"That, in the opinion of this conference, the evils inseparable from the system of gratuitous medical relief, administered at the out-door department of hospitals and in free dispensaries, can be in great measure met by the establishment on a large scale of provident dispensaries, not only in the metropolis, but throughout the kingdom, and by improved administration of the Poor-law medical relief."—The resolution was seconded by the Rev. J. F. KITTO.

Mr. HARDY cited the case of the Marylebone Provident Dispensary, as showing that the provident principle did not receive much encouragement in London. The public had subscribed only £50 last year to that institution.

Mr. STANSFELD, M.P., who was called on by the Chairman, after a few remarks, said: I should like to express my general sympathy with the views of those who have called the conference together, and with the purposes of the Charity Organisation Society, to which I have given much and close attention, though only for a period of nine months past. You, sir, and probably every one whom I have the honour to address, have doubtless given a much longer attention to this great and important subject. But what has struck me has been this: the close connexion between the problem of the best administration of national Poor-law and the problem of the best administration of the national voluntary charity of this country. They are both in one sense a charity. The one is the organised, although not always the best organised, charity of the nation collectively. The other is that very complex system which is founded on the generosity and liberality of successive generations, to which this Society seeks to give something like an organisation fitting and suited to the necessities and exigencies of the time. Now, you have felt, and I have felt, this very strongly. The principle of the Poor-law is a very benevolent one; it is one that reflects immense credit on the country and its history; and it is this: that no subject of this realm shall suffer for want of the necessities of life—that if a case of positive necessity is brought home to those who have to administer the Poor-law, that that case, deserving or undeserving, must be relieved. Well, in the administration of that law we have found—as you have found in the administration of charities—that it is open to very great abuse. It is a principle that we cannot abandon, any more than you can interfere with the motives and inducements of those who wish to give to those who want; but it is a principle the carrying out of which must be watched with great patience and care; so much so, indeed, that I believe a great many of those who have given their minds with the closest attention to the question of Poor-law administration, are almost inclined to say to themselves and the public that the main functions of those who have the administration of that law is to take care to do as little harm as possible. Now I know that that is a very great

and difficult function, and it is one which occupies my daily thought. But I am not prepared, and you have shown that you are not prepared, to be content with such a solution of the Poor-law difficulty, or of that of the administration of voluntary charity. To be content with such a solution, so far as the Poor-law is concerned, would be simply to apply the workhouse test, and to refuse out-door relief, no matter how much required or what the exigency of the case, and, in the administration and organisation of voluntary charity, to give the attempt up altogether. I hold such philosophy to be wholly insufficient for the facts with which we have to deal, and with the conditions of mind and belief fortunately of our country. I am fully conscious of the extreme difficulty of the problem. It is a problem, as has been well said, of very great complexity. Our first duty in administering a charitable law, or great voluntary charities, is, as far as possible, to take care that we do not do mischief, and to be actuated by a desire to do good. It is, I say, necessary that we should carry our labours a step farther, and endeavour, by every amount of consideration and effort that may be necessary in devising an organisation, to do something more than minimise the evils of a system which is intended to work positive good. Now, while it is hardly fitting that I should deal with the details of the question, I should like to say I am unable to see how, so far as the administration of the Poor-law is concerned, we can succeed in solving our problem without your assistance. I think there are relations between the administration of the Poor-law of this country and the administration of its voluntary charities which are beginning to dawn upon people's minds, but to which we do not see our way quite clearly as yet. But they will have to be considered, if we would in the future make even the administration of the Poor-law adapted to the conditions and exigencies of the time. And I look with great sympathy upon the establishment and operation of the Charity Organisation Society, because it has set itself to that task. I trust that those who conduct its operations here and elsewhere will endeavour to think out that part of the subject; and I can only assure them, so far as the department with which I have the honour to be connected is concerned, that I shall always be ready, and more than ready—thankful—to discuss with them any practical proposals which may occur to them with that object in view. You must allow me to refer for a moment to the observations which have been made by Dr. Acland. While not accepting the high eulogium which he was pleased to pass upon me, I can say that my thoughts are given with no sparing of time or labour to the question of the administration of the department with which I am occupied just now, and also to the question of future legislation. It is not for me, of course, to undertake to commit my colleagues upon the subject of the legislative measures of next Session, or to anticipate what may be the views of Parliament upon the subject; but I may, perhaps, say to you without indiscretion that, as far as I am myself concerned, I should be much disappointed if an opportunity were not to offer itself to me of putting forward some legislative proposals next Session upon the subject of the sanitary administration of the country; and that I am at this time busily engaged, at any rate, in putting into shape proposals which I hope to submit to my colleagues upon that subject. The relations between the administration of the Poor-law and the administration of what may be called the health of the country are intimate and known to us all, and are evidently well understood by those who took part in the discussion to-day. I was very much struck by the suggestion of Dr. Acland, that it might be well in the organisation of the hospitals and infirmaries, whether belonging to unions, or parishes, or to towns, that provision should be made for the treatment in the same building and under the same management, not only for those who were professedly and acknowledgedly paupers, but also of the great mass of the community who could not afford in their own homes to secure the conveniences and accommodation which might be afforded to them in the hospitals, even if they contributed somewhat to the support of those institutions. That suggestion shall have my careful consideration. I do not propose to continue the discussion. I was desirous simply of accounting for my presence on this occasion, which I believe is not a very usual circumstance; but I may say I almost volunteered to come. I felt strongly the usefulness of this discussion. I was convinced that great good would come of it, and also that I should derive much more benefit from it by being here than by reading any report of the discussion, however full and accurate it might be. I have only to thank you for the kind manner in which you have listened to the few remarks which I have made.

The CHAIRMAN said he was anxious to state, before putting the resolution, that he was not opposed to any extension of the hospital system. What he was anxious for was that those excellent institutions should be made more efficient and more perfect in their administration for the relief of the sick poor than they now were. He had been asked to state that the Charity Organisation Society was ready to assist the managers of the hospitals by making inquiries as to the cases registered

on the books of their out-patient wards. He had taken some trouble some years ago to investigate such cases, and found that twenty per cent. of the cases so registered had given false addresses; so that it was impossible to trace them. The great object they all had in view was to do the greatest amount of good to the greatest number. They desired, so far as they could, to make the poor of the country self-reliant and self-dependent, to place them in a position in which they could depend upon their own wages for their own support; and for that purpose it was necessary to remove from them temptation, and to teach them to rely on their own strong arms and their own providence, so that they might make provision for one of those contingencies of life to which all were exposed, and which it was as necessary to provide against as against fire or any other calamity which was common to all.

The resolution was put and carried, and the proceedings terminated with a cordial vote of thanks to the chairman.

## SPECIAL REPORT ON THE SANITARY STATE OF SCARBOROUGH.

[Continued from page 677.]

THE results of the examination of the suspected waters in use at Londesborough Lodge, which are given below, are opposed to the idea that they are contaminated by sewage-matter, or that they are likely to have been the cause of enteric fever in the members of the Scarborough party. The water obtained from the pump contains a larger amount of free ammonia than is found in good water; but it appears to have been used solely for washing purposes, and was not likely to reach the table in any shape. Besides, it is possible that the free ammonia may be otherwise accounted for than by sewage-contamination. Irrespectively of the special interest in the results of the examination of these waters, the following report of Dr. Ferrier, who has had large experience in the application of the zymotic test, will be found of value.

I have been requested (says Dr. Ferrier) to examine, chiefly in regard to its zymotic properties, the so-called Bristol water, such as was in use as the ordinary drinking-water in the household of Lord Londesborough during the visit of H.R.H. the Prince of Wales. The water is said to be obtained from the Hot Wells at Clifton, and is put into bottles while hot, in which it is stated to remain perfectly clear and good for many years.

The sample sent me was remarkably clear and free from sediment, and without odour or taste. Microscopical examination failed to detect any indications of the presence of organic matter or organisms. It was tested as to its zymotic or septic power, after the method described in the Thirteenth Report of the Medical Officer of the Privy Council. With regard to the theory and significance of this physiological test of the purity of water, it will be necessary to explain the principles on which it is founded, and the method of carrying it out.

It consists in the addition of a few drops of the water under investigation to a relatively large quantity of an organic fluid particularly prone to decomposition (but which, without this addition, will remain perfectly unchanged for an indefinite period), and in observing the comparative rapidity with which the liquid becomes altered, and the amount of development of zymotic organisms which the water is capable of effecting. Reasons were given in Dr. Sanderson's report for regarding the organisms (chiefly bacteria), whose existence is thus manifested as the pioneers, if not the active agents, in the putrefaction of nitrogenous substances. My own subsequent investigations have convinced me that putrefaction is entirely due to these organisms. My experiments have shown, in direct contradiction to the recent experiments of Hoppe-Seyler and others, that such putrescible fluids as hydrocele fluid, when collected in such a manner as to avoid contamination with septic germs, may be subjected to the prolonged action of heat which is stated of itself to be able to induce putrefaction, and yet remain after the full period in which such changes are said to take place entirely unaltered, and as free from signs of putrefaction as when collected; whereas the same fluid, when the same precautions against contamination are not observed, becomes putrid in the course of a week. The natural vehicle for the distribution of these septic germs, apart from direct contact, is water. Their existence in water cannot be demonstrated by any other method than the zymotic test, and so great is the delicacy of the test that but very few waters can stand it successfully.

So great, however, are the differences in the zymotic property of different waters, as the results given below will illustrate, that, when equal quantities of the test-liquid are impregnated with an exactly

equal amount of the suspected waters, and placed under the same conditions, the evolution of organisms and the changes in the test-liquids effected by the different waters will, in a given time, vary from absolute barrenness and crystalline clearness of the test-liquid, to a dense milky-white opacity and thick bacteria scum.

I may say that from numerous experiments I have found that the zymotic properties of water stand in close quantitative relation to the degree of contamination with sewage and decomposing organic matter generally. The zymotic test, therefore, taken along with chemical analysis, will indicate not merely the amount of contamination with septic products, but also the amount of activity of such water in inducing still further similar changes in organic liquids and tissues. In typhoid stools, at the period at which they are said to be most active, myriads of bacteria are to be seen.

It must not, however, be understood from the remarks made, that there is any causal connexion implied between the amount of bacteria in water and disease. All that can be as yet definitely stated is that, if water be contaminated with sewage and typhoid dejections, it must also contain these organisms in large amount. And if perchance such diseases as typhoid fever be disseminated through the agency of specific germs in water contaminated with the dejections, we may yet be able to detect them in the myriads of organisms developed by the method above described.

I have selected, as a standard of comparison, water obtained by the fusion of a clear block of Wenham Lake ice. In the first set of experiments, I compared the Bristol water with this and with a specimen of water supplied by one of the metropolitan water-companies. Three charged eprouvettes, containing five cubic centimetres of Pasteur's solution (containing sugar, tartrate of ammonia, and yeast-ash), were impregnated on December 8th with five drops, from a capillary pipette, of Wenham Lake ice-water, Bristol water, and London water. They were placed in an incubator standing at a uniform temperature of 100 deg. F. They were examined on December 11th, with the following result.

1. Eprouvette impregnated with Wenham Lake ice-water: Perfectly clear, and of crystalline purity, without any indication of organisms.

2. Eprouvette with Bristol water: Also clear; but, when carefully compared with the Wenham Lake ice eprouvette, a very slight diminution of the transparency could be detected.

3. Eprouvette with water of London water-company: Test-liquid quite opalescent, and covered with a thick bacteria-scum.

The results obtained were very striking, and indicate that the Bristol water is a water of remarkable purity, approaching very nearly the standard of Wenham Lake ice-water. These results, in my opinion, leave no ground for attributing any noxious effects to the Bristol water, and entirely discountenance the idea of sewage-contamination.

I also received for examination samples (1) of water from a pump in the kitchen at Londesborough Lodge, (2) Scarborough town water from the supply-pipes at Londesborough Lodge, and (3) the same water from the supply-pipes at Mr. Dale's house.

The pump-water had a slightly turbid appearance. It had no appreciable odour or taste. Microscopical examination revealed the presence of a considerable quantity of suspended particles of granular matter, but no organisms. The Scarborough town water was clear; but in both specimens a considerable quantity of deposit was observed. In the deposit—particularly in that from Mr. Dale's house—I detected specimens of *anguillula fluviatilis*, one or two *entomostraca*, numerous *diatoms* and *mycelium filaments*, together with a considerable quantity of organic debris.

The zymotic test was applied in the manner above described, and a comparison instituted between the Bristol water, the Scarborough waters, and a specimen of distilled water slightly contaminated with water supplied by the — London Water Company. At the end of 72 hours, as in the former case, after cultivation at a temperature of 100 deg. Fahr., the results were as follows.

Eprouvette with Bristol water.	Test liquid in
" " Scarborough water from Lon. Lodge.	all quite clear,
" " " " Mr. Dale's house.	and without
" " water from pump at Londes. Lodge.	any apprecia-
" " contaminated distilled water.	ble difference
	between them.
	Distinct zy-
	motic haze.

These results show that the Scarborough water, though open to considerable improvement in regard to its filtration, comes quite up to the highest standard of purity, and leaves little or nothing to be desired in regard to its freedom from zymotic germs.

As in the case of the Bristol water, I have no hesitation in saying that it appears to me thoroughly vindicated from all suspicion of sewage-

contamination, and that there is no reason for considering the water at Londesborough Lodge inferior to the water supplied to the rest of the town.

DAVID FERRIER, M.D.

Chemical analyses have been specially made for us of—

1. Bristol water from Londesborough Lodge;
2. Water from the pump at Londesborough Lodge;
3. Town water from the pipes at Londesborough Lodge;
4. Town water from the pipes at Mr. Dale's house.

The following are the results in grains per gallon.

	Fixed.	Solid Contents. Volatile.	Total.	Free Ammonia.	Organic Nitrogen.
No. 1...	56	22.4	78.4	.0007	.0017
No. 2...	7	5.6	12.6	.0224	.0086

No. 4...	16.8	12.6	29.4	.0007	.0017

These results show that the samples Nos. 1, 3, and 4, are of excellent quality; but the amount of free ammonia in the sample No. 2 suggests the probability of contamination with drainage from a cesspool, or some similar receptacle of domestic refuse. This water is, moreover, decidedly turbid.

The proportions are also stated below as parts in 100,000, conformably with the official reports of the Rivers Pollution Commissioners.

	Fixed.	Solid Contents. Volatile.	Total.	Free Ammonia.	Organic Nitrogen.

We select the following account from amongst the numerous communications which have been received by us on the subject of the sanitary condition of Scarborough. Our correspondent, who, from his connexion with public medical practice at Scarborough down to a recent period, is entitled to attention, gives the results of his experience during three and a half years' continuous observation of the sanitary state of the town.

He says that this favourite watering-place is in need of many improvements, and that enteric fever is always to be found there to a greater or less extent. He qualifies the statement by avowing that his professional acquaintance with facts has been almost entirely confined to the northern part, and that he is therefore unable to say anything definite concerning the south side, which is the newer and more fashionable part of the town, although he has heard more than once that its drainage system and other sanitary arrangements are anything but perfect. The district which is most fertile in disease is to the north side of Westborough, Newborough, and Eastborough, together with yards running off the south side of Newborough and Eastborough, and the parts of the town called Landside and Quay Street. Falsgrave, a suburb of Scarborough, about a mile to the west of the Bar, also furnishes many cases.

The drains are not kept in proper order in many of the worst parts of the old town, nuisances and all sorts of organic matters being allowed frequently to block up for a long time the iron gratings at the points where the street-gutters lead into the underground drains; and this, in hot weather, gives rise to most disgusting effluvia. The blocking of the drains, says our informant, has been most common in the streets that are steep, and where water and other fluids have carried the solid matters before them in greater quantity than in those streets which are more level. The organic matters very frequently consisted of fish and the material used to bait the fishermen's lines. The drains at the gratings often give issue to very offensive odours, independent of the organic matters collected on them; and our correspondent says he has frequently noticed, on the sands of the south side, near the Grand Hotel, sewage running across the sands into the sea, caused either by the exit-drainage being leaky, or the drains not being carried far enough out. Offensive smells from the drains in the yards and closes are also frequently noticeable, the cause being an infrequency and insufficiency of flushing. The water-supply is obtained from a distance of three miles; but in the old town it appears that many of the houses must depend on their supply from neighbouring pumps, which are sometimes found to be in the immediate vicinity of privies and pigstyes. Privies are often built quite close to the houses, and, in the yards, are common to different dwellings. They are not, as a rule, in a good condition; and often give rise to very unpleasant effluvia.

The better parts of the old town, consisting of streets chiefly in-

habited by the more respectable members of the working and artisan class, are of recent construction, and are built on a tract of ground running east and west, at the north part of the old town. This part is still called the common, owing to its having been one for many years. On remarking the unusual preponderance of zymotic disease in this quarter, our correspondent was informed, by one who knew Scarborough well, that, up to a few years back, rubbish of various kinds had been carted on to this land and left there, and that the houses had been built without the deposit having been perfectly removed. If this be true, it is quite easy to see how hot weather would cause emanations of a very unhealthy character to arise through the flooring of the houses, supposing the deposit became a lamp in the wet seasons of the year; and these houses had no cellars, the wooden floors being merely a few inches above the soil. The worst cases of enteric and scarlet fever occurred in this quarter.

Our correspondent next points out a state of things which must exercise an unfavourable effect on the neighbouring inhabitants. The open ash-pits and middens in the worst parts of the old town exist in considerable numbers, and often make known that existence by the emission of most offensive smells. In these receptacles, refuse of all kinds is put, including in many cases fecal matter. The contents of these uncovered ash-pits, when exposed to the action of the sun in hot weather, are frequently found to be most offensive. Piggeries exist in several parts of the old town, and, in more than one instance, in the middle of a thickly populated part. On two or three occasions our correspondent has brought these evils under the notice of the Inspector of Nuisances, but nothing, as far as he has seen, was ever done to remedy them, except in a temporary way. With regard to the stench often emitted from the drains, our correspondent attributes this in a certain degree to the action of the tide forcing the gases back; and expresses an opinion that, perhaps, this could not be altogether provided against. But, in addition to this, he has been led from his own observation to believe that many of the drains are insufficiently flushed. The water-supply from Cayton, which, as already observed, is two miles and a half from the centre of the old town, is good; but it is not laid on to the houses in some districts, and the supply is obtained from pumps, where the hard water of the wells is liable to contamination by sewage. In 1868, our correspondent attended about thirty cases of typhoid fever; and, in 1869, scarlatina was unusually prevalent, assuming in many cases quite a malignant type, inasmuch as three deaths from this disease have been known to occur in a house within a few days of each other. The part of Scarborough already alluded to as the common, was more afflicted with scarlatina than any other district of a similar size; and typhoid fever was also, our correspondent thinks, in preponderance in this quarter. A plan of Scarborough will show that the streets where these diseases obtained greater sway lie close together; and this is the part where the refuse is said to have been deposited, and not to have been properly cleared away when the ground was built upon. These streets are Upper and Lower Hoxton Road, Upper and Lower Nelson Street, Cambridge Street, Bow Street, Brook Square, Brook Street, Albion Street, and Barwick Street, and a few hundred yards west of these streets, Roscoe Street, where some very bad and fatal cases of scarlatina were attended by our correspondent. But, indeed, cases both of typhoid and scarlatina occurred in every street of the old town during his residence there, although many more of the latter than of the former disease. I do not believe, the writer says, that during my time in Scarborough a single close or yard in the place failed to furnish cases of scarlatina; and in most of them, if not in all, fatal cases of this affection occurred. Our correspondent is not able to speak from experience of Lendborough Lodge or its vicinity; neither does he profess to know much professionally of the neighbouring villages, excepting Falsgrave, which was comparatively healthy. There is no medical officer of health in Scarborough; and recent events, our correspondent suggests, will have demonstrated the need of what this town should have possessed years ago.

## ASSOCIATION INTELLIGENCE.

### SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEDICAL MEETINGS.

THE next meeting of the above Society will be held at the Greyhound Hotel, Croydon, on Thursday, December 21st. Dr. COLES will take the Chair at 4 P.M.

The dinner will take place at 6 P.M.

Papers, etc., are promised by Mr. S. Lee Rymer, Dr. Jeaffreson, the Chairman, etc.

HENRY T. LANCHESTER, M.D., *Honorary Secretary.*

Croydon, December 6th, 1871.

## SPECIAL CORRESPONDENCE.

### LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

*Poor-Law Medical Officers and Private Practice.—The Vacant Physicianship at the Great Northern Hospital.*

A QUESTION of much interest to Poor-law medical officers has recently been under discussion by the Board of Guardians for the Toxteth Park Union. The district officers in that parish were originally appointed under the usual conditions—viz., a fixed salary, with liberty to engage in private practice. A few years ago, however, the guardians resolved to pay a larger salary, with the understanding that the medical officers should devote their entire services to the parish, excluding any other professional engagements. There appears to have been a difference of opinion as to the comparative merits of the two plans; and, at their last meeting, a majority of the Board decided that for the future the original system of allowing private practice should be adopted. In the parish of Liverpool, which may be considered not only one of the largest, but also one of the best regulated unions in the kingdom, especially as regards the medical department, each of the two plans has been tried for several years respectively. The result has been to satisfy the Select Vestry that, on the whole, the plan of allowing their medical officers to carry on private practice is the more satisfactory. The appointments are sought for by a class of practitioners of longer standing, and such are more likely to retain the office somewhat permanently. Their position as established practitioners is considered to be a guarantee for their professional efficiency, and for a deeper feeling of responsibility than may be felt by young beginners, who perhaps “are here to-day and gone to-morrow,” and who frequently take the appointment as a temporary expedient only.

The election of Dr. Glynn as Physician to the Royal Infirmary has created another vacancy at the Northern Hospital. The existing laws of this institution render any candidate ineligible who has not been in actual practice for three years, or who has within six months of the date of appointment practised midwifery or pharmacy. The stringency of this regulation has proved so deterrent to applicants, that, on the last occasion when a vacancy was advertised, not a single candidate offered himself. To remedy this, it was in contemplation to remove all restrictions whatever beyond the possession of a physician's diploma, and thus to throw open the appointment to all grades of the profession. This proposal, however, was disapproved of by the profession of the town, as calculated to lower the status of the office and the prestige of the institution; and the trustees, in deference, no doubt, to an expression of opinion at a recent meeting of the Medical Institution, have given notice of a modification of the laws, which reduces the requirement as to previous practice from three years to two, and removes altogether the restriction as to midwifery and pharmacy prior to the appointment—retaining, however, the requirement that these branches of practice shall be relinquished by the successful candidate from the time of his election. Under this more reasonable arrangement, there is little reason to fear that eligible candidates will not be forthcoming.

### MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

*St. Mary's Hospital and the Royal Infirmary.—Ovariectomy.*

I SPOKE in my last letter of the proposed amalgamation of St. Mary's Hospital and the Royal Infirmary. I have since personally inspected St. Mary's Hospital, and feel that one or two of my former statements require qualification. In the first place, St. Mary's Hospital is not practically a maternity hospital at all, for, the number of beds being inadequate to the demand, there is no room for lying-in women; and, in the second place, the sanitary aspect and construction of the hospital are so bad as to render it absolutely necessary that it should be moved to more suitable premises. This will doubtless be carried out, and the more readily as they possess property to the amount of £40,000; and, if the amalgamation with the Infirmary do not take place, they will unquestionably build elsewhere. Indeed, the vicinity of Stevenson's Square has been talked of for the purpose.

As a sample of the work done at this hospital, I may mention that there were six operations last Wednesday, including excision of the hip, vaginal lithotomy, excision of the elbow, and vesico-vaginal fistula. Mr. Whitehead, who performed the resection, makes little use of splints, simply placing the limb in a convenient position, and using

sandbags to keep the muscles quiet. In the case of excision of the hip, which was performed upon a little girl six years of age, he secured the feet by a crossbar attached to the foot-rail of the bed, so as to ensure equal length in the two limbs, leaving the leg otherwise quite free.

It is certainly remarkable that, with such bad sanitary surroundings (their nearest neighbour is a choked up *cul-de-sac* of a pestilential canal), the surgeons of this hospital should have had such success with ovariectomy. Thus they have had six successful cases this year, out of a total of seven—a result which Dr. Lloyd Roberts and his colleagues largely attribute to seeking favourable meteorological conditions for the operation. At the present moment, we learn, there are seven cases at the hospital waiting to be operated upon, the present season not being considered suitable.

## VIENNA.

[FROM OUR OWN CORRESPONDENT.]

*The General Hospital.—Rare Form of Cardiac Hypertrophy.—Extra-uterine Fœtation.*

It is now extremely cold for so early a part of the winter, and the cold already equals the most intense of last winter in England. Under this trial, however, the wards and lecture-rooms in the General Hospital are warm and comfortable, but not stuffy, and there is a total absence of hospital odour. Considering that one hundred and fifty years have elapsed since this hospital was built, its construction reflects the greatest credit on the enlightened architect. Whether this excellence is due solely to the plan of spreading the building and dividing it into separate divisions, or not, it is difficult to say, but no doubt it is largely due to it. The double windows, too, enable the ventilation to be carried on excellently. One of the outer upper divisions is inclined inwards, and admits the air into the space betwixt the two windows, while one of the upper divisions of the inner window consists of a metal rose. Thus anything like a direct draught is avoided—one of the objections to the open-window system most strenuously urged. That there is no draught down on the patients' heads here, I can testify from repeated observations. The air, too, is warmed by being first admitted into the space betwixt the outer and inner window, and again by the metal rose, which is, of course, of the temperature of the ward. In the clinical medicine lecture-room, the patients are wheeled directly from the adjoining ward in their beds, without disturbance or exposure to the draught of a passage or corridor. This plan, too, enables the patient to be seen by all the class; and with such large classes as are here, no other plan could achieve this; while the Professor (Duchek) lectures and draws the outline of the internal organs on the skin with a black crayon. How far all these advantages are neutralised, or even more than counterbalanced by the prolonged exposure—of a rheumatic fever patient with pericarditis, etc., for instance—is highly questionable. But a great deal of the advantage of Vienna lies in its material, as seen very well in the laryngoscopic class. What an advantage it must be to have a large *clientèle* of patients all well trained to hold themselves steady under examination, must be obvious even to a mind of the most unimaginative character. When the patients are being examined, twelve or fourteen at a time, and putting their vocal cords on the stretch by a prolonged A, which sounds extremely like the bleat of a sheep, it is almost difficult to persuade oneself that there is not a flock of ewes and lambs in the neighbourhood.

A very rare form of cardiac hypertrophy presented itself in the dead-house lately. It was that single variety which is found without obstruction to the flow of blood in one form or another, and is alone entitled to be considered as a disease *per se*. Niemeyer describes it as being found in commercial travellers who eat and drink a great deal; and Oppolzer attributes it to more active and more frequent contraction of the heart from the action of alcohol, while at the same time he mentions its extreme rarity. The patient was a man of unusual corpulence, and died from a rupture of the middle left cerebral artery. There was no atheroma of the vessels; the kidneys were merely slightly infiltrated with fat, but very little; there was no obstruction in the aorta; there was no valvular disease, and yet the heart was at least twice the ordinary size; the walls of the left ventricle were massive and perfect in their structural integrity. It was obvious that the hypertrophied heart had been too powerful for the cerebral vessels, and thus led directly to the patient's death. On inquiring as to the causation of this singular hypertrophy, the answer given was that the man had been a great eater and drinker, and that it was an instance of the form of hypertrophy described by Niemeyer under that head. The great rarity of hypertrophy of the heart as a disease itself is now universally admitted. Flint, in his work on Heart-Disease, gives a case of this form of hypertrophy; and the oozing of blood in the agony mentioned by him was also found in the

case here, as well as the effusion of blood on opening the calvarium. In Flint's case, the patient was a young man of active, and apparently of regular habits; and the disease is even more unaccountable than in the case here.

A case of extra-uterine fœtation was recently admitted into the Vienna Hospital. When the patient was dying, it was determined to make an effort to save the child. The Cæsarean operation was performed, and the child gasped once or twice, but did not show further signs of life. The child was found quite free in the peritoneal cavity, and the *post mortem* examination revealed the fact that the impregnated ovum had dropped into the fold of Douglas, and attached itself to the peritoneum. The umbilical cord was found surrounding the uterus in several coils, while it is supposed that the child escaped from the membranes two or three months ago. The Fallopian tube was so much spread out as to be undistinguishable as to its distal termination. The parts will be subjected to a careful examination, in order to see how the placenta became formed, and the vascular supply acquired from parts not originally destined for the purpose. As evidencing the innate power of self-support and growth in the impregnated ovum, without the aid of the organ specially furnished for its reception and growth, the case is one of no ordinary interest.

## REPORTS OF SOCIETIES.

### SURGICAL SOCIETY OF IRELAND.

FRIDAY, DECEMBER 8TH, 1871.

JAMES H. WHARTON, M.D., President, in the Chair.

*President's Address.*—The PRESIDENT delivered an address inaugural to the present session. He commenced by a reference to the good work done by the Society even thirty years ago, enumerating the most important communications made at that time by the leading surgeons of Ireland. Yet, notwithstanding what had been already achieved, he believed there was still abundant opportunity for the Surgical Society, and kindred associations, to aid in the advancement of medical science. Among those topics to which the attention of the members might most usefully be directed, the President particularised the subjects of the treatment of cancer; the modes of arresting hæmorrhage, especially that of torsion; the section of the neck of the femur in cases of bony ankylosis of the hip-joint; the treatment of croup by tracheotomy, as advocated by the illustrious Trousseau; and the great subject of hygiene, in all its bearings. Dr. Wharton's address concluded with some general remarks as to the method of working to be pursued in the coming session, and with an expression of his sense of the honour done him in being selected to fill the presidential chair of the Society.

*Rectal Polyp.*—Mr. CROLY presented two polypi of the rectum which he had recently removed from a very young girl. Repeated hæmorrhages had attracted her mother's attention. The larger of the two tumours was highly vascular, and was attached to the mucous membrane by a long pedicle.

*Mammary Tumour.*—An example of chronic mammary tumour was also shown by Mr. CROLY. He had removed the growth from the left breast of a woman, aged 35. That the case deserved the name of "chronic," appeared from the affection having been of two years' standing. A smaller tumour of the same kind had lately commenced to grow in the right mamma.

*Disease of the Tibia, etc.*—Mr. CROLY exhibited a section of the tibia and fibula of a young man, in whose case he had performed amputation through the lower third of the femur for disease of the tibia. The morbid process had extended to the knee-joint, for its cartilages were found to be ulcerated.

*Radical Cure of Hernia, etc.*—Mr. JOLLIFFE TUFNELL described a case illustrative of Syme's modification of Wutzer's operation for the radical cure of hernia. The patient, a butler, was 37 years of age, but he had experienced laxity of the abdominal rings from early childhood. Some time ago, a hernia came down on the left side; this was afterwards increased by the occurrence of long-continued bronchitis, and finally became irreducible. In 1869, Mr. Tufnell for the first time saw the case. There was now a large scrotal entero-epiplocele on the left side. In accordance with the patient's express wish, an operation for the radical cure was performed under chloroform on the 18th of May last. The steps of the operation were identical with the procedure recommended by Mr. Syme. On June 20th, convalescence was completed. Mr. Tufnell examined the parts again on December 5th, and at that date no trace of hernial protrusion could be detected on the felt side. On the opposite side, however, an increasing tendency to relaxation was noticed, and the hernia there had become almost scrotal. In

concluding the history of this interesting case, Mr. Tufnell briefly summed up the advantages of the operation, and referred to Dr. Porter's case, published in the *Dublin Quarterly Journal* for 1863.—Dr. PORTER had found the operation as modified by Mr. Syme a most satisfactory one. Its simplicity was a leading point in its favour. He believed that even in cases where a radical cure was not effected by its means, the patient was placed in a better condition for treatment by trusses.—Dr. BUTCHER would observe caution in extending operative action as far as the internal ring, and so wounding the peritoneum proper. The portion of this serous membrane that had become invaginated in the canal, in his opinion, lost its character as a delicate structure, and might therefore bear injury without much risk of peritonitis being incurred.—Mr. CROLY alluded to the small mortality after Wüster's or Syme's operation, and urged the more frequent adoption of the radical cure by Irish surgeons. He thought the peritoneum escaped wounding in the process, the invagination of the skin of the scrotum being effected with the lining membrane of the canal.—Mr. L'ESTRANGE asserted that radical cures had been attained, without any operative interference whatever, by the continued wearing of suitable trusses.—Dr. WALSH mentioned a successful case treated by a truss adapted by Mr. L'ESTRANGE.—Dr. FLEMING said that it was almost impossible to fairly return a hernial sac which had remained in the scrotum for a lengthened period, and had been much pressed on by different trusses. In such cases, a certain pathological condition became established, for the sac gradually underwent attenuation. Under these circumstances, the contents of the sac, though not the sac itself, remained returnable.—Mr. EDWARD HAMILTON believed that the sac of a hernia of old standing which had been long down, could not be reduced. It had lost its anatomical peculiarities.—Mr. STAPLETON agreed with the opinions expressed by Dr. Fleming and Mr. Hamilton; but, though the sac of an old hernia became adherent, it might still be pushed up and invaginated.

Before the meeting adjourned, three patients, on whom Mr. Croly had performed tenotomy for contraction of the knee-joint, were examined by the members and visitors present. Owing to the late hour, a communication on the subject was deferred to the next meeting of the Society.

#### CLINICAL SOCIETY OF LONDON.

FRIDAY, DECEMBER 8TH, 1871.

J. BURDON SANDERSON, M.D., F.R.S., Vice-President, in the Chair.

*Tumour in Left Half of Floor of Fourth Ventricle, with Tumour in Cerebellum.*—The patient, a child two years of age, came under Dr. BROADBENT'S care amongst the out-patients of St. Mary's Hospital on March 14th, 1870. Three weeks previously, the child had begun to have what the mother called "screaming fits", which only came to an end when it was utterly exhausted. She slept well, ate ravenously, drank much; the bowels were confined; and every morning there was vomiting before any food had been taken. On examination, the left side of the face was found to be paralysed; and the left eye was not closed, either voluntarily or in winking, or when the cornea was touched. There was no marked strabismus; but this eye could not pass the median plane of the orbit outwards. The right hand was clenched and agitated while the child cried, and was continually in motion when it was quiet. The left hand was quiet, or moved naturally. Both legs were continually in motion; the right most. There was little change during the five weeks in which the patient was under observation. The paralysis of the sixth nerve and of the portio dura of the seventh became more marked, and the loss of power in the right hand more evident, the rigidity and agitation continuing. The screaming, vomiting, and constipation were little affected by the treatment, which consisted in the application of a leech behind the left ear, and in the administration of an aperient powder, and first of chloral in ten-grain doses every four hours, later, of belladonna in full doses. The child died on August 20th. A tumour was found to occupy the left half of the floor of the fourth ventricle, involving, as was anticipated, the common nucleus of the sixth and portio dura of the seventh nerves, shown by Stilling and Lockhart Clarke to be situated in the fasciculus tectus; and in a less degree the already decussated motor tract from the right half of the body. Another small tumour was found in the left hemisphere of the cerebellum; but, as all the symptoms were explained by the tumour in the floor of the fourth ventricle, it had probably not given rise to any characteristic symptoms. Both tumours were gliomatous in structure.—Mr. BRIDENELL CARTER asked if any ophthalmoscopic examination had been made. He had had under his own care a case of paralysis of the portio dura, in which the only symptom was epiphora. His assistant thought it due to obstruction of the nasal duct, when he noticed that lacrymation took place on one side of the

face only.—Dr. BROADBENT replied that circumstances prevented an ophthalmoscopic examination from being made. In answer to Dr. C. T. WILLIAMS, he said that he had not thought there was a tumour of the cerebellum, because all the symptoms were explained by that on the floor of the fourth ventricle.

*Heart-Disease.*—Dr. HABERSHON narrated two cases of disease of the heart. The first instance was that of a young man aged 30, who had been accustomed to great muscular exertion, and in whom the aortic valves were rendered imperfect by continued strain. Hypertrophy and dilatation of the left ventricle ensued; and the physical signs of aortic obstruction and regurgitation were accompanied by urgent dyspnoea and by paroxysms of angina pectoris. The mitral valve at length became so stretched that it ceased to act as a valve, and the indications of pulmonary and abdominal congestion became apparent. At this time a triple sound was audible at the apex of the heart, and continued for several weeks—till, in fact, the right ventricle became accustomed to the additional strain thrown upon it, and beat in unison with the left ventricle. After a time a systolic *bruit* at the apex replaced the triple sound. The triple sound was explained by the want of synchronous action between the two ventricles. It had been noticed in rupture of the mitral valve, and also in cases of contraction of that valve; and in this instance it occurred for a short period in connection with an overstrained mitral valve. The patient became slowly exhausted by the increased embarrassment of the heart and by dropsy.—Dr. ALTHAUS said that he had had a similar case under his care in which opium was followed by anasarca of the legs and total suppression of the urine. Acupuncture was had recourse to, but it was followed by gangrene of the part and death.—The PRESIDENT remarked that the diagnostic interest of the case lay in the diagnosis between triple sound and thinned mitral valve, as the cases in which the triple sound had been previously mentioned were those of small mitral valve. He should like to know if the condition of this valve had lasted long.—Dr. C. J. B. WILLIAMS believed that the aggravation in the first case was due to the fresh complication of aortic disease. Mercury was very valuable in heart-disease with visceral congestion, and especially in combination with digitalis. Opium did much more harm than good, and also chloral, as the physical condition of the heart prevented sleep. Digitalis fortified the weak and dilated heart.—Dr. BROADBENT thought that there was more than one condition leading to reduplication of the first sound. A want of synchronism between two ventricles might explain it, and could be demonstrated by the double stethoscope. He believed in the utility of mercury alone or combined. He had seen marked benefit resulting from its use.—Dr. LANGDON DOWN believed that reduplication of the first sound resulted from want of synchronism in the heart's contraction.—Mr. LAWSON asked in what position the patient was tapped, as it might have accounted for the syncope occurring in consequence of the operation.—Dr. HABERSHON, in reply, said he agreed that the results of opium in such cases as his was not satisfactory, but it was given in the present instance for angina. It, however, aggravated the general symptoms. Mercury had been given with benefit in the form of the black oxide. Especially in mitral disease mercury was most useful, and especially in combination with squills and digitalis. The mitral valve apparently began to yield when the pulmonary and other visceral congestion took place. He did not think that irregular contraction of the chordæ tendineæ would produce the triple murmur. He did not know in what position the patient was tapped, as he was not present at the operation.

The second instance was that of a child aged 11, in whom severe cardiac disease, affecting the mitral valve, followed an attack of rheumatism. Three years previously he had the first attack, and had been ill for a fortnight before his admission into Guy's Hospital on Feb. 22nd, 1871. There was pain in the limbs; and, in the plane of the mitral, a loud systolic *bruit*, and a less distinct presystolic one, were audible. He improved in health till about the middle of April (12th), when the presystolic *bruit* became more distinct; and this indication of fresh disease was shortly followed by severe brain symptoms; vomiting and delirium, with hemiplegia on the left side, suddenly supervened; symptoms of great prostration followed, with convulsive movements of the right side; and, when consciousness was regained, he cried out and complained of pain in the head and in the spine. On the third day he began to rally, and in ten days the paralysis began to lessen, but the hand and arm recovered before the foot and leg. The presystolic *bruit* also ceased, and the systolic mitral *bruit* alone remained audible. He left the hospital relieved on June 24th. The presystolic *bruit* was probably due to deposit upon the mitral and consequent obstruction, and increased deposit led to augmentation of the sound. The cerebral symptoms were traced to embolism; and soon after the onset of these symptoms the presystolic *bruit* was diminished in intensity, as if the mitral, relieved of a portion of fibrinous deposit, acted more freely.

The retrocession of the hemiplegic symptoms was in the inverse order from ordinary hemiplegia, from apoplexy; namely, that the arm recovered before the leg and the hand, and the feet before the shoulders and the hips. Very little medical treatment was permitted in this case, and it illustrated in a remarkable manner the natural subsidence of the symptoms of disease as the circulation of the brain accommodated itself to the temporary obstruction.

## CORRESPONDENCE.

### BRITISH MEDICAL BENEVOLENT FUND.

SIR,—Will you kindly permit me to make a Christmas appeal to your readers on behalf of the British Medical Benevolent Fund, a charity which I venture to say has a strong claim on the sympathies of all our brethren.

Help *promptly* given, help *quietly* given, is, I may say, a distinguishing feature of this Benevolent Fund, and I might add help *carefully* given, and help *inexpensively* given; for I can assure you, that I know of no society whose meetings are more regularly or better attended than the monthly committee meetings at 11, New Burlington Street, while the only paid official is the collector. The cases relieved by grants during the past eleven months are one hundred and two; but inasmuch as some of these cases represent large families of children, the number assisted is really much greater. The sum of £834 has been thus expended, and to meet the cases which arise this month (one of the heaviest in the year), our Treasurer had at its commencement a balance remaining of about £20 only.

If it were not for fear of trespassing on your space too largely, I should like to give the details of a few cases, as specimens of the want and misery your readers are asked to assist in alleviating—want and misery all the more bitterly felt, as in most instances the sufferers have been at some time or other in comfortable, if not in affluent, circumstances. Donations or subscriptions, however small, will be most thankfully received by the Treasurer, Dr. Hare, 57, Brook Street, the Honorary Financial Secretary, C. S. Webber, Esq., Upper Berkeley Street West, or by

Yours, etc.,

STAMFORD FELCE, *Honorary Secretary.*

12, Chippenham Road, Paddington, W., Dec. 12th, 1871.

P.S.—Articles of clothing for men, women, or children, I am always glad to receive for our applicants.

### THE COMING RACE.

SIR,—The letter of Mr. Berkeley Hill, in the *BRITISH MEDICAL JOURNAL* of November 25th, giving an account of the shortcomings of the candidates for the diploma at an examination of the Royal College of Surgeons, induces me to bring under your notice the serious complaints made by two intelligent and anxious students at Guy's Hospital. As I am the medical attendant of their families, they naturally speak to me on the subject. Certainly there does appear just reason for their observations on the manner of conducting the lectures on anatomy. Their complaints run thus. For the first two or three weeks, Mr. — gave lectures on the formation of bone, etc., so minutely as apparently to delay the more important instruction—at least to beginners. Mr. — followed, and has gone over the bones of the upper and lower extremities, lingering long on many individual bones and minute points, with frequent repetition; thus making the lectures extremely tedious to intelligent students, as most of the points must necessarily come again under observation with the muscles, etc. A whole lecture of one hour was given on the clavicle (the account of which might be read over in any dozen books treating upon it in that space of time), and an equal time upon other small bones; thus rendering the lectures dull and tiresome, and inducing indifference. This long delay has brought to an abrupt close this part—the very groundwork of anatomical knowledge—leaving the difficult bones of the head and face, the vertebrae, the walls of the chest and pelvis, to be feebly mastered or altogether passed over. This will, doubtless, prove a serious and permanent detriment, as they may appear to be advancing in their studies when the groundwork is wholly unsound; and, should the whole course proceed in the same manner, the result must be most unsatisfactory. Piecemeal anatomy cannot be correct. The neglect of weekly examination is another serious drawback; for the observation of the mistakes of others their correction affords a more general insight into the subject, induces attention, and enables the lecturer to ascertain the advance of the student, and practises the latter in a correct and ready manner of answering questions. The very ex-

tensive scope of the present examinations at the various boards, and their practical nature, render necessary great exertion on the part of the teachers, and a correct method, so that the students may obtain a fair and continuous outline of the subjects which they have to master. Should the present staff not be sufficient, there are many ambitious young men who might be obtained, whose post should be to direct and to ascertain the progress of the students.

I think that lecturers will be indebted to the first year's students a course of lectures on the bones, which ought to be given next summer session, when some comparative anatomy might be fairly brought on to make up for the present loss. I have advised that the students should ascertain that some more continuous plan will be carried out, otherwise I shall deem it my duty to advise that they enter at some other hospital.

A copy of this has been forwarded to the Treasurer and to the *BRITISH MEDICAL JOURNAL*, suggesting that a reporter be appointed to visit the various schools, and state in what manner the instructions were given, and report to the profession.

I am, etc.,

London, Dec. 1st, 1871.

THOS. JOHNSON.

### SEWAGE AND ENTOZOA.

SIR,—In answer to Dr. Cobbold, I wish to state that I have nothing to do with angry feelings, and that abuse is not argument. I stated three facts; viz., 1. That Dr. Cobbold did not know Croydon, or he would not have fallen into the strange error he had done in calling it swampy and low-lying. 2. That his prophetic utterances regarding the spread of entozoa by irrigation received no support from the experience derived from the continuance of sewage-irrigation on the farms of the Croydon Local Board, one of which has now been in operation for more than eleven years. 3. That the health of the inhabitants living in the district which is irrigated is undeniably good, as evidenced by returns from the Registrar, which show ten deaths to twenty-seven births during the half year ending Michaelmas last.

Dr. Cobbold cannot dispute one of these points, but adduces the theoretical and fanciful evidence which was given before committees of the House of Commons. The evidence was totally disproved at the time, and shown to be either unnecessary or improbable. The evidence then adduced had no weight with the judges, and their verdict proves the opinion of six distinct committees in Lords and Commons to be against Dr. Cobbold's witnesses. Dr. Cobbold puts forward their evidence as if it had not been completely disproved. Dr. Letheby's idea that "irrigated land is always a fetid, swampy morass" is an offspring of his imagination.

If Dr. Cobbold will visit our fields (unsatisfactory though they be), I shall be glad to show him that there are two sides to a question—a fanciful and a real one—and that those most engaged in the work will be the best judges, unless they are determined to be deceived, which I am not.

In conclusion, allow me to say that I never supposed that Dr. Cobbold had anything to do with patents in this matter.

I am, etc.

ALFRED CARPENTER, M.D.

Croydon, December 4th, 1871.

## OBITUARY.

### THOMAS S. BARRY, ESQ.

MR. THOMAS STAWELL BARRY, Staff-Surgeon in Her Majesty's Army, died in London on November 21st. He was educated in Ireland, and was a pupil of St. George's Hospital Medical School. He entered the service in 1855, and had his promotion as Staff-Surgeon in 1869. He was seized with jaundice two months since, when on sick leave; and succumbed to this, complicated with an attack of pneumonia. He went through the Crimean campaign, and served in India and in New Zealand.

### THOMAS SCARD, M.R.C.S.ENG.

MR. SCARD died at Balmain, near Sydney, New South Wales, aged 35. He left this country a few years since as surgeon to an emigrant ship; and finding a good opening for his profession at Sydney, he settled there, and had obtained considerable practice. He was obliged to undergo a painful operation, for which chloroform was administered, and he died suddenly under its influence. It is thought there might have been latent disease of the heart. When the last Australian mail left, a coroner's inquest was in progress, and a *post mortem* examination ordered.

## ROBERT SMITH, ESQ., ABERDEEN.

MR. ROBERT SMITH, of Aberdeen, was born August 12th, 1800. In 1818, he began the study of medicine in Aberdeen, under Dr. Skene, Professor of Medicine in the Marischal College and University. In 1819, he discontinued his medical studies, and followed for a time a mercantile life. In 1828, he resumed his professional studies; and in 1833 became a Member of the Royal College of Surgeons of London. He commenced to practise in Aberdeen in 1834. In 1841, Mr. Smith was elected a Medical Officer of the Aberdeen Dispensary. From 1841 to 1871, he was occupied in the active duties of professional practice. His last illness began suddenly, while he was writing a medical prescription in the house of a dispensary patient. Consciousness never returned after the apoplectic attack; and on November 18th, he died, at the age of 71. Mr. Smith, during many years, was Curator of the Museum of the Aberdeen Medico-Chirurgical Society.

## JOHN DAVIDSON, M.B., C.M.

It is with the deepest regret that we have to record the death, on the 5th inst., from typhoid fever, of Mr. John Davidson, M.B. and C.M., one of the resident physicians'-assistants at the Middlesex Hospital. Mr. Davidson was a native of Aberdeen, where he received his preliminary education at the Grammar School and University. He commenced the study of his profession in 1866 in the University and at the Royal Infirmary. Here he soon became highly esteemed both by the professors and members of the hospital staff and by his fellow-students, among whom he occupied a high position, from his theoretical and practical professional knowledge, and constantly took the leading part in movements affecting the privileges or the recreations of the students. Many men of his time will remember him as one of the most active leaders in the hard-fought struggle which ended in the election of the present Lord Rector of the Aberdeen University; as one who was ever at the head of any social diversion that might happen to be made to lighten the labour of the long Scotch winter session; and as the man who was better able, perhaps, than any other to maintain the reputation of the University on the field or on the river. After completing the usual four years' study at Aberdeen, during which time he carried off many of the highest prizes, he graduated in medicine and surgery with the highest honours in 1870. Soon afterwards he went to Vienna, where he studied clinical medicine and surgery for a short time; and on his return was appointed Junior House-Surgeon at the Middlesex Hospital. This post he held for six months, after which he was for the same length of time Senior House-Surgeon, and subsequently one of the Resident Physicians'-Assistants. While attending assiduously to his duties in the last-named capacity he was seized with typhoid fever; the attack being pronounced and severe from the first, but still not alarmingly so until about the twenty-first day, when grave congestion of the lungs supervened, and carried him off two days afterwards on the forenoon of the 5th inst.

In John Davidson, the Middlesex Hospital lost a man whose name will long be remembered within its walls with the profoundest respect and the most sincere regret. As a member of the resident staff, he is said to have been one of the best house-surgeons there for many years; intelligent, energetic, and obliging, he was extremely popular with all, from the surgeons and physicians down to the patients—a straightforward honest man. By those who knew him most intimately, he was held in especial estimation for the strength of his affection, his extreme unselfishness, and his strong abhorrence of everything mean or ungentlemanly.

It was his intention, we believe, to undertake a London career as a surgeon. Had he been spared to do so, we are confident that his future would have been very successful, if not brilliant.

## MEDICAL NEWS.

UNIVERSITY OF LONDON.—Second M.B. Examination, 1871. Pass Examination.

## First Division.

Allchin, William Henry, University College  
Bath, James Barry, Middlesex Hospital  
Carr, William Ward, University College  
Carter, Alfred Henry, University College  
Elkington, Ernest Alfred, General Hospital, Birmingham  
Humphreys, John H., General Hospital, Birmingham, and University College  
Lyell, Robert Wishart, King's College  
Lucas, Richard Clement, Guy's Hospital  
Southcote, Henry Edward, Guy's Hospital

## Second Division.

Barr, William Bennett, B.Sc., St. Bartholomew's Hospital

Cumberbatch, Alphonso Elkin, St. Bartholomew's Hospital  
Durham, Frederic, Guy's Hospital  
Harding, Alfred William, B.A., University College  
Ingoldby, Joseph Theodore, Guy's Hospital  
Martin, Henry Newell, B.Sc., University College  
Paget, William Smith, Liverpool School, and University College  
Read, Charles, University College  
Wall, Alfred John, St. Mary's Hospital  
Westcott, William Wynn, University College

## Examination for Honours.—Medicine.

## First Class.

Allchin, William Henry (Scholarship and Gold Medal), University College  
Southcote, Henry Edward (Gold Medal), Guy's Hospital

## Second Class.

Lyell, Robert Wishart, King's College  
Elkington, Ernest Alfred, General Hospital, Birmingham

## Third Class.

Carr, William Ward, University College  
Carter, Alfred Henry, University College } equal.  
Lucas, Richard Clement, Guy's Hospital

## Obstetric Medicine.

## First Class.

Lucas, Richard Clement (Gold Medal), Guy's Hospital  
Southcote, Henry Edward, Guy's Hospital

## Second Class.

Humphreys, John H., General Hospital, Birmingham, and University College  
Lyell, Robert Wishart, King's College

## Third Class.

Carter, Alfred Henry, University College  
Elkington, Ernest Alfred, General Hospital, Birmingham  
Allchin, William Henry, University College

## Forensic Medicine.

## First Class.

Elkington, Ernest Alfred (Gold Medal), General Hospital, Birmingham

## Third Class.

Lyell, Robert Wishart, King's College  
Southcote, Henry Edward, Guy's Hospital

## M.D. Examination.

Black, John Gordon, University of Durham College of Medicine  
Carter, Charles Henry, B.A., University College  
Curnow, John (Gold Medal), King's College  
Haynes, Frederic Harry, St. Bartholomew's Hospital  
Irvine, James Pearson, B.A., B.Sc., University College  
Pollard, Frederic, St. Thomas's Hospital  
Poore, George Vivian, University College  
Richards, William Alsept, King's College  
Seaton, Edward, St. Thomas's Hospital  
Snow, Herbert Lumley, University College, and Queen's College, Birmingham  
Tayler, George Christopher, St. Bartholomew's Hospital  
Thomas, John Davies, University College

## Logic and Moral Philosophy only.

Alford, Henry James, University College  
Barnes, Edgar George, St. George's Hospital  
Hall, Francis de Havilland, St. Bartholomew's Hospital

## B.S. Examination.

## Second Division.

Aveling, Charles Taylor, St. Thomas's Hospital  
Carr, William Ward, University College

ROYAL COLLEGE OF SURGEONS.—The following members of the College, having undergone the necessary examinations for the Fellowship on the 22nd, 23rd, and 24th ultimo, were reported to have acquitted themselves to the satisfaction of the Court of Examiners; and, at a meeting of the Council, on Thursday, the 14th instant, were admitted Fellows of the College.

Butlin, Henry Trenham, Camborne, Cornwall: diploma of membership dated November 12, 1867.

Hardwicke, Junius, Rotherham: June 3, 1844.

Higgins, Charles, Hambleton, Hants: April 21, 1868.

Oldham, Charles James, Brighton: January 20, 1870.

Pope, Herbert William, Carlisle: November 16, 1869.

Putbridge, Samuel Bowen, Her Majesty's Indian Army: August 5, 1851.

Renelle, Richard, Forest Hill: April 22, 1868.

Wyman, William Sanderson, Putney: April 25, 1862.

Four candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for twelve months.

At a special meeting of the Dental Board, on Tuesday, the 12th instant, Mr. Samuel Hamilton Cartwright, of Old Burlington Street, having undergone the necessary examination, was admitted a Licentiate in Dental Surgery; his diploma of membership bearing date May 7th, 1867.

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, December 7th, 1871.

Kilner, Walter John, Bury St. Edmunds

The following gentlemen also on the same day passed their first professional examination.

Collier, Nicholas C., King's College  
Edwards, John Ellis, Guy's Hospital

### MEDICAL VACANCIES.

The following vacancies are announced:—

**BALLINROBE UNION**, co. Mayo—Medical Officer for the Ballinrobe Dispensary District: £100 per annum.  
**BRIGHTON AND HOVE DISPENSARY**—Two Surgeons.  
**CARNARVONSHIRE AND ANGLESEY INFIRMARY AND DISPENSARY**, Bangor—House-Surgeon: £80 per annum, board and lodging.  
**CORK UNION**—Medical Officer for the Blackrock Subdistrict of the Cork Dispensary District: £100 per annum.  
**EARLSWOOD ASYLUM FOR IDIOTS**—Assistant Medical Officer: £150 per annum, board and apartments.  
**EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN**—Physician.  
**EAST RETFORD UNION**, Notts—Medical Officer for the Dunham District.  
**EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY**—Physician: Assistant-Physician.  
**EXETER LYING-IN CHARITY**—Two Surgeons.  
**GOREY UNION**, co. Wexford—Medical Officer to the Workhouse, Infirmary, and Fever Hospital: £100 per annum.  
**JERSEY GENERAL DISPENSARY**—Resident Visiting and Dispensing Medical Officer: £100 per annum, furnished rooms, attendance, coal, and gas.  
**KILBURN, MAIDA VALE, AND ST. JOHN'S WOOD GENERAL DISPENSARY**—Resident Medical Officer: £100 per annum, furnished rooms, £45 per annum for a dispenser and servant, coal and gas.  
**LIVERPOOL**—Public Analyst for.  
**MANCHESTER**, Township of—Medical Officer for St. Michael's District: £170 per annum.  
**METROPOLITAN FREE HOSPITAL**, Devonshire Square—Hon. Surgeon.  
**MIDDLESEX HOSPITAL**—House-Physician.  
**MIDDLESEX COUNTY LUNATIC ASYLUM**, Hanwell—Medical Superintendent of the Female Department.  
**NORTH STAFFORDSHIRE INFIRMARY**, Hartshill—House-Physician: £80 per annum, board, furnished apartments, and washing.  
**NORTH WALES COUNTIES LUNATIC ASYLUM**, Denbigh—Assistant Medical Officer: £80 per annum to commence, rooms, board, and washing.  
**NUNEATON UNION**—Medical Officer and Public Vaccinator for the Nuneaton District: £55 per annum, and extra fees.  
**OLDHAM UNION**, Lancashire—Medical Officer for Workhouse: £65 per ann.  
**PENISTONE UNION**, Yorkshire—Medical Officer for the Workhouse: £30 per annum, and extra fees. Medical Officer for the Penistone District: £21 per annum, and extra fees.  
**POCKLINGTON UNION**, Yorkshire—Medical Officer for the Market Weighton No. 2 District.  
**ROYAL INFIRMARY**, Manchester—Senior House-Surgeon: £84 per annum, board, etc.  
**ROYAL SOUTH LONDON DISPENSARY**—Honorary District Surgeon.  
**ST. MARVBONE**, Parish of—Medical Officer for St. John's Registration District: £120 per annum.  
**ST. PANCRAS AND NORTHERN DISPENSARY**—Resident Medical Officer: £100 per annum, and allowance for coal, servants, etc.  
**SOUTHAMPTON**—Medical Officer of Health.  
**SOUTH STAFFORDSHIRE AND WOLVERHAMPTON HOSPITAL**—Secretary.  
**STOCKWELL FEVER HOSPITAL**—Resident Medical Superintendent: £400 per annum, unfurnished residence, coal, and gas.  
**SUFFOLK GENERAL HOSPITAL**—Physician.  
**TOXTETH PARK TOWNSHIP**—Medical Officer for District No. 2: £250 per annum.  
**UNIVERSITY COLLEGE HOSPITAL**—Assistant Obstetric Physician.  
**WEST BROMWICH DISTRICT HOSPITAL**—House-Surgeon: £70 per annum, board and residence.  
**YEATMAN HOSPITAL**, Sherborne—Dispenser: £50 per annum.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\***BRACH**, Fletcher, Esq., appointed House-Surgeon to the Hospital for Sick Children, Great Ormond Street, *vice* Wm. Sankey, Esq., resigned.  
**CANTON**, G. Anderson, Esq., appointed Surgeon-Dentist to the Royal Portsmouth, Portsea, and Gosport Hospital.  
**CARTER**, Alfred H., M.B., appointed Medical Registrar and Pathologist to the General Hospital, Wolverhampton, *vice* A. Bottle, M.D., resigned.  
**CLARKE**, Arnold, Esq., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Raferagh Dispensary District of the Carrickmacross Union.  
**DE MERIC**, Henry Eugene, Esq., appointed Junior House-Surgeon to the Royal Free Hospital.  
**FERGUSON**, A., L.R.C.P. Edin., appointed Parochial Medical Officer for Peebles, Stobo, and Manor.  
\***LINDSAY**, J. Murray, M.D., Medical Superintendent of the Female Department of the Middlesex Lunatic Asylum, Hanwell, appointed Medical Superintendent of the Derby County Lunatic Asylum.  
**MCEWAN**, William, M.B. and C.M., appointed Medical Officer for the Tenth District of the City Parish of Glasgow.  
**MACKELLAR**, John, M.D., appointed Parochial Medical Officer for North Uist, Inverness-shire.  
**MACNICOL**, Hugh, L.F.P.S. Glasg., appointed Medical Officer and Public Vaccinator for the New Pitsligo District of the Parish of Tyre, Aberdeenshire.  
\***MATTERSON**, William, M.D., appointed Consulting Physician to the York Lunatic Asylum, in the room of \*Caleb Williams, M.D.  
**O'BRIEN**, Daniel, M.D., appointed Medical Officer to the Workhouse of the Ennistymon Union, co. Clare.  
**RYAN**, Laurence Joseph, L.R.C.P. Edin., appointed Medical Officer and Public Vaccinator for the Oulart Dispensary District of the Enniscorthy Union, co. Wexford, *vice* Michael Joseph Sheridan, M.D., appointed to the Wexford Dispensary District of the Wexford Union.

\***SHIPMAN**, George, Esq., appointed Medical Officer to the District of the Grantham Union, *vice* Charles Ferneley, M.D., resigned.  
**SLATER**, John S., Esq., appointed House-Physician to St. Thomas's Hospital, *vice* E. Cox, Esq., resigned.  
**SMITH**, J. Priestley, Esq., appointed House-Surgeon to the Birmingham and Midland Eye Hospital, *vice* F. H. Hodges, Esq., resigned.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

#### MARRIAGE.

**CAMPBELL**, Peter, M.D., Bridge of Allan, N.B., to Phebe, daughter of the late Peter Rainford RIGBY, Esq., Liverpool, at St. Paul's Presbyterian Church, Westbourne Grove, London, on November 28th.

#### DEATHS.

**BOXWELL**, Richard, M.B., late H.E.I.C.S., of Abbeylieux, Queen's County, on November 28th.  
**COLLINGS**, Adolphus, M.D., formerly Surgeon 40th Regiment, at Guernsey, aged 56, on December 1st.  
**GREENHEAD**, Charles E., M.D., at Watford, aged 90, on November 24th.  
**WILLIAMS**.—On December 8th. aged 31, Caroline Anne, wife of \*John Williams, M.D., of Sudbury, Suffolk.

**DONATIONS, BEQUESTS, ETC.**—"W. X." has given £1000 to the National Hospital for the Paralysed and Epileptic.—"W. S. N." has given a third annual £1000 to the Charing Cross Hospital.—Mr. T. Edmett has bequeathed £3000 to the West Kent Infirmary and Dispensary; and £1000 to the Kent County Ophthalmic Hospital.—Mr. J. H. Beattie, of Surbiton, has bequeathed £500 to the Hospital for Incurables.—Captain Jillard, of Frome, has bequeathed £500 to the Shepton Mallet Hospital.—Mr. W. Welch has bequeathed £300 to the General Hospital, Birmingham.—Mr. John Palmer has bequeathed £100 to the Queen's Hospital, and £100 to the General Hospital, Birmingham.—"E." has given £50 to St. Thomas's Hospital.—The General Hospital, Birmingham, has received £100 under the will of Mr. Benjamin Chandler.—Miss Gibson, of the Lower Close, Norwich, has transferred £100, new Three Per Cents., to the Trustees of the Norfolk and Norwich Hospital.—Mr. Emmanuel Mocatta has bequeathed £500 each to Beth Holim Hospital, the Jews Hospital at Lower Norwood, the Cancer Hospital, the Hospital for Consumption, University College Hospital, and several non-medical charities.—St. Leonard's Hospital, Sudbury, has received £100 under the will of Mr. Townsend of Bures.

### BOOKS, ETC., RECEIVED.

The Clinical Thermometer: its Lessons and Teachings tentatively expressed in Numbers. By L. C. McElroy, M.D. New York: 1871.  
Elementary Treatise on Physics, experimental and applied. For the use of Colleges and Schools. Translated and edited from "Ganot's Elements de Physique" (with the author's sanction), by E. Atkinson, Ph.D., F.C.S. Fifth Edition, revised and enlarged. Illustrated by a Coloured Plate and 726 Woodcuts. London: 1872.  
Statistical Report on the Health of the Navy for the year 1869.  
General Representation on a Complete Readjustment and Modification of Mr. Hare's Plan. By Archibald E. Dobbs, M.A. London: 1871.  
Inaugural Address delivered at the Opening of the Twenty-second Annual Meeting of the American Medical Association, held at San Francisco, California, May 1871. By Alfred Stille, M.D. Philadelphia: 1871.  
On Clinical Education: the Introductory Address to the Clinical Session, 1871-72, at the Queen's Hospital, Birmingham. By Furneaux Jordan, F.R.C.S. London: 1871.  
A National Technical University for Great Britain and her Colonies; or, how to Utilize Greenwich Hospital and the Obsolete Charities. A Letter to the Right Hon. W. E. Gladstone, M.P., from the Executive Committee of the proposed National University for Technical and Industrial Training. London: 1871.  
National Disease. Remarks upon the Prevailing Epidemic of Small-pox, its Cause and Prevention: with Notes on Public Health, Eruptive Diseases, etc. (amongst mankind and the animal world). London and Newcastle-upon-Tyne: 1871.  
Physiology as a branch of General Education. A Graduation Address delivered on August 1st, 1871. By John Hughes Bennett, M.D. Edinburgh: 1871.  
Report on the Sanitary Condition of the Whitechapel District, for the quarter ending 30th September 1871. By John Liddle. London: 1871.  
First Report of the Medical Committee of the Charity Organisation Society; with Rules for Provident Dispensaries. London: 1871.  
The Second Annual Report of the Committee appointed to establish a "Hospital Sunday", for the benefit of the principal Medical Charities connected with Cumberland and Westmorland. Carlisle: 1871.  
Instructions to the Inhabitants of the Borough of Bury as to Means to Preventing the Spread of Small-pox and Scarlet Fever. By Thomas B. Bott, M.D.  
What the People say about the Children, and what the Children say about Canada. By Maria S. Rye. London: 1871.  
Preliminary Notice on the Treatment of Emphysema of the Lungs by Artificial Expiration. By J. B. Berkart, M.D. London: 1871.  
The Bombay Health Officers' Report for the Third Quarter of 1871.  
Transactions of the Fourth Annual Meeting of the American Otological Society. Observations on the Therapeutic Value of Chloral. By Alexander Edward M' Rae, C.M., M.B. Edinburgh: 1871.  
Association of Certifying Medical Officers of Great Britain and Ireland. 1871.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY**..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**..... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**.—Medical Society of London, 8 P.M. Mr. Thomas Bryant will exhibit some Drawings and make some Remarks Illustrating the Process of Cell-Growth in the Operation of Skin-grafting; Dr. Ogle (Derby), "Preventive Medicine or Medical Reform: not Parliamentary, but Particular and Individual."

**TUESDAY**.—Pathological Society of London, 8 P.M. The following specimens will be exhibited:—Mr. Lawson: Case of Blood Cyst. Mr. Spencer Watson: Ulcer of Eyelid, removed by Dr. Swift Walker. Mr. A. Norton: Ulceration of Trachea. Dr. Thorowgood: Large Salivary Calculus removed by Operation. Dr. Southley: Caseous Degenerative Disease of Suprarenal Capsules. Dr. Peacock: Plugging of Middle Cerebral Artery. Dr. Payne: Hæmatoma of Muscle. Mr. Goodhart: Casts from the Intestine.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 35, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

FOR replies to questions concerning Poor-law medical questions, see Poor Law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Marshall, Dublin.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**SECRETARY**.—It certainly does not seem fair to those practitioners who hold the degree of M.D. from Universities, that the title of "Dr." should be used by others. Still, in the case of members of Colleges of Physicians, custom and courtesy have so far prevented the misuse of the title, that a return to its strict limitation would be a very difficult matter.

Dr. A. W. Edis (London).—The matter shall receive our attention.

## EXTRACTS FROM A DOCTOR'S DIARY.

**IV**.—Reading in the papers about flogging at Newgate, recalls the good old times when, for disgraceful conduct, soldiers received fifty lashes, until philanthropic doctors, who had equal conception of the magnitude of the crime and the light nature of the punishment, interfered. Having attended many parades, and treated the soldiers afterwards, I remembered to instance of unobserved torture or of cruelty. A few drops of oil and water-dressing comprised all required. Excepting by the cruel remounted, the typical cruel garrotter, pain as a rule would unflinchingly be endured.

**V**.—I do not regret that the practice of marking with the letters B, C, and D, has been abandoned. Possibly the same reason who limits re-education is a frequent occurrence. I could witness at the simple operation, but beyond the tell-tale letters, nothing appeared objectionable, notwithstanding the outcry against infamous branding. If all officers and men on joining were tattooed on the wrist, in the one instance it would be a proud mark of distinction; in the other, desertion and recidivism would be checked.

**VI**.—What a pity it is that well-intentioned ladies and others should interfere with sanitary measures which have been most carefully and practically considered by eminent statesmen, philanthropists, and medical men. We do not attempt to touch the clergyman, the lawyer, or the philosopher; it would be the height of impudence, neglecting our own difficult studies, to go out of our way to obstruct others. The learned cannot change his spots, nor man his nature. Punish us lawyers by all means; train the adulterers; but, above all, lend your aid to

prevent the daughter from sneaking out after dark from a comfortable home to join the ranks of the "unfortunates," either for pleasure or for gain. None can deny the ability of the Contagious Diseases Acts to do this, as well as to check the spread of disease, and to help and succour many poor girls, the majority of whom have been driven to degradation and shame through poverty, seduction, and early training. Paramount reigns home-influence; and when you meet fast girls in society or elsewhere, read a history of the want of a mother's care, or of innate vicious tendency. How quiet the barracks are now compared to former years. When the wind whistles cold, the rain beats against the window, and we shiver over the winter fire, the sound of the poor girls' feet wearily pacing up and down the parade is comparatively seldom heard. Years ago, sometimes young officers joined with a young lady in black silk and a gold chain; and on one occasion, a girl, in a fit of jealousy, tried to hang herself in the quarters; but such events and delirium tremens are things of the past. Many ladies, several over the climacteric, or hard and without children, unsympathetic, indirectly increase syphilis, and punish innocent children with an inheritance of scrofula, hydrocephalus, cancer, and insanity. With honest virtuous mothers, as well as with the pariahs who, in preference to starvation, pursue a calling often to them repulsive, this delicate difficult subject has been talked over; and, taking all in all, my candid opinion, after long and laborious investigation, is that the Contagious Diseases Acts, when properly understood and judiciously carried out, will improve both the health and the morality of England.

**OLD MORTALITY**.—On the south side of the altar in Kensington Church were tablets stating that David Middleton, Sergeant Surgeon to George III, died December 29th, 1785, aged 85; his wife died at the age of 89. Dr. John Ash, for some time an eminent physician at Birmingham, who subsequently resided in London, and was well known in literary circles, was also buried here. Dr. Matthew Baillie was buried at Duntisbourne, Gloucestershire. Cheselden at Chelsea Hospital. Hunter at St. Martin's-in-the-Fields; re-interred in Westminster Abbey, where also Sir Theodore Mayerne is interred. Francis Glisson, who discovered the capsula communis, born in 1597, was buried on the west side of Fleet Market, now Farringdon Street.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

## STOPPING TEETH.

SIR,—In answer to your correspondent Dr. Evans, I beg to say that to prepare and stop a tooth properly with gold—the only reliable stopping—takes a far longer time to learn, is much more tedious, and requires greater manipulative skill, in many instances, than any other operation in surgery. If, however, Dr. Evans is anxious to try his hand at tooth-stopping, the best amalgam for general purposes may be obtained at Messrs. Ash and Sons, 8, Broad Street, Golden Square, London. For further information, I would refer him to *Tomes's Dental Surgery*, pp. 302-488.

I am, etc., CHARLES GAINE, M.R.C.S.,  
Dental Surgeon to the Royal United Hospital, Bath.

Bath, December 13th, 1871.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Liverpool Daily Post, Dec. 5th; The Northampton Herald, Dec. 9th; The Liverpool Weekly Albion, Dec. 9th; The Shield, Dec. 9th; The Scarborough Gazette, Dec. 9th; The Birmingham Daily Post, Dec. 8th; The Salopian, Dec. 9th; The Brighton Daily News, Dec. 11th; The North British Daily Mail, Dec. 13th; etc.

COMMUNICATIONS, LETTERS, &c., have been received from:—

The Earl of Lonsborough, London; Dr. Broadbent, London; Dr. Lombe Athill, Dublin; Dr. Cornelius B. Fox, Scarborough; Dr. Bishop, Paris; Mr. W. Stuart, London; Dr. Aitkin, Woolston; Dr. Wolfe, Glasgow; Mr. W. A. Collings, Guernsey; Mr. Dale, Scarborough; Mr. Jessop, Leeds; Our Berlin Correspondent; Dr. Ferrier, London; Dr. A. T. H. Waters, Liverpool; Our Vienna Correspondent; Dr. J. G. Swayne, Clifton, Bristol; Dr. Patrick Heron Watson, Edinburgh; Mr. George Street, London; The Rev. T. Scard, Bishops Waltham; Mr. Peter Robertson, Glasgow; Mr. A. Smith, Northampton; Dr. Williams, Sudbury; Mr. H. Spencer Smith, London; Mr. Gascoyen, London; A Member; Mr. Annandale, Edinburgh; Mr. W. A. Dunkin, Brockton, Shrewsbury; Dr. B. Hunt, Birmingham; Mr. Henry Greenway, Plymouth; Our Dublin Correspondent; Dr. C. B. Brearey, Scarborough; Dr. P. Frank, Cannes; The Secretary of the Clinical Society; Dr. Alex. Ogston, Aberdeen; Dr. Protheroe Smith, London; Dr. T. L. Brunton, London; Dr. Wilks, London; Mr. Richard Hunter, Dartford; U. P., Tring; Mr. James E. Adams, London; The Secretary of the Pathological Society; The Secretary of the Birmingham and Midland Eye Hospital; Dr. Hermann Beigel, Vienna; Mr. H. Phelps, Bristol; Mr. William Sharp, Great Grimsby; Mr. Wm. Grant, Wolverhampton; Dr. Andrew Clark, London; Dr. Carpenter, Croydon; Dr. A. W. Edis, London; Dr. Paul, London; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Mr. Holthouse, London; The Secretaries of the Association of the Medical Officers of Health; Dr. Savage, Birmingham; Mr. M. C. Soutter, London; Dr. Cheadle, London; Dr. Johnson, London; Mr. Francis Mason, London; Mr. Heckstall Smith, St. Mary's Cray; Dr. Stamford Felce, London; Mr. C. ## REMARKS

ON

## THE INSTRUMENTS DESIGNED FOR EXPLORING GUN-SHOT WOUNDS,

WITH A VIEW TO DETECT BULLETS OR OTHER FOREIGN BODIES SUSPECTED TO BE LODGED IN THEM.

By T. LONGMORE, Esq., C.B.,

Professor of Military Surgery at the Army Medical School, Netley.

THERE are two distinct surgical operations which have to be adopted in proceeding to treat cases of suspected lodgment of foreign bodies in gun-shot wounds, as well recent as chronic wounds. The first is that of *exploration* of the wound, or the operation of determining with certainty that the supposed foreign body is lodged in it, as well as its exact situation; the second is that of *extraction*, or the operation of removal of the foreign body, after the fact and site of its lodgment have been established. The means of exploring for a foreign body, and of extracting it, are often combined in one and the same instrument. Nearly all bullet-extractors admit of being used for purposes of exploration; but, on the other hand, various instruments have been devised as explorators which do not answer the purposes of extractors. These latter instruments have been designed to meet the special requirements of particular cases.

Under ordinary circumstances, whenever a gun-shot wound is large enough to admit of the insertion of the surgeon's finger, this alone should be used for exploring purposes. No artificial instrument can give the same amount of information, or afford information so precise, with regard to the lodgment of foreign bodies and their nature, as the surgeon's finger can give. Should the opening of entrance of the projectile be too contracted to admit of its easy insertion, as will sometimes happen when the wound has been caused by a bullet of small diameter, such as the Chassepôt rifle-bullet or a pistol ball, the surgeon's finger should not be thrust in with undue force, which will be hurtful in many ways, but an incision to the necessary extent should be made at the margin of the wound, extending through the fascia, to facilitate its ingress. When, after insertion, the finger fails to reach sufficiently far, owing to the depth of the wound, the exploration is often assisted by pressing the soft parts, especially if the wound be in one of the extremities, from an opposite direction toward the finger-end.

In making the exploration, the finger should be inserted slowly and steadily towards the deepest part of the wound. During its passage, the surgeon should carefully observe whether any foreign body appears to be pushed before it, or to be lying by the side of the track of the bullet, and should note any other peculiarities of the wound. He should also ascertain whether the end of the track is reached; and, if this is found to have been arrived at, a careful circular sweep of the finger-end will then usually settle if any, and what, foreign bodies are lodged. The surgeon should not withdraw his finger until the course the projectile has taken, the injury it has done, the complications of the wound such as the presence of foreign bodies, and, in such a case, their kind and situation, have been decided by him; the exploration will then be completed by one operation, and a second insertion of the finger for the purpose, which is always irritating to a patient, will be avoided. Nothing can be simpler than the exploration of a gun-shot wound by the finger; yet, simple as it is, very different results may follow the operation according to the manner in which it is performed; if done carelessly and impulsively, it will be done roughly, will cause proportionate bruising, pain, and, after all, convey only imperfect information; if done thoughtfully, these hurtful effects will be avoided, while the knowledge conveyed by the manipulation to the surgeon will be definite, and generally of special utility in determining the proceedings to be afterwards adopted.

If the finger be not sufficiently long to reach the bottom of the wound, even when the soft parts have been approximated by pressure from an opposite direction, and when the lodgment of a projectile is still suspected, or some other point of doubt remains to be solved, such as the direction the projectile has taken in the latter part of its course, we are compelled to make a further exploration by other means. Generally, a long silver probe, that can be bent if required, and that can be guided into a definite direction at the will of the surgeon, will be found to be the best substitute for the finger. The probe should be used with great discretion, for, without care, it may readily be made to inflict injury on

vessels or on other structures which have escaped from direct contact with the ball, but have returned by their elasticity to the situations from which they had been pushed or drawn aside during its passage. It seems hardly necessary to observe that these directions for examining gun-shot wounds apply only to such as penetrate the extremities or extend superficially in other parts of the body; where a missile has entered any of the important cavities, such exploration would obviously be as useless as it would be mischievous.

In the majority of cases of gun-shot wounds there will be no difficulty in detecting the lodgment of foreign bodies, especially heavy ones, as bullets and fragments of shell, when the examination has been made early by the finger in the manner described. Sometimes, when the finger in the wound fails to find a lodged projectile, the particular spot in which it is lying may be detected simply by relaxing the muscular tissues, so as to give a loose and pendulous condition to the parts concerned, and then lightly tossing up the flesh at different points from below with the tips of the fingers. A bullet lodged among the soft parts will occasionally make its presence known, under such an action, by the impulse which its weight communicates to the top of one of the fingers when the parts which have been shaken upwards return to their previous position. Sometimes a gentle kneading pressure in the neighbourhood of the injury, assisted by information derived from the sensation of the patient, will lead to the detection of such a foreign body. Sometimes, as mentioned in the English official history of the Crimean war, when a lodged bullet could not otherwise be discovered, it was found by passing the flat palm of the hand down a limb. Its presence was occasionally detected in this way when the points of the fingers had utterly failed to feel it.

We come now to the cases in which the exploration by the surgeon's finger is altogether impracticable, and in which the use of the probe is attended with so many sources of doubt as to prevent any satisfactory conclusion in respect to the lodgment or absence of foreign bodies from being arrived at. These difficulties sometimes happen with wounds in situations where they might be least expected to be met with, but generally occur in such as have their terminations at or near some of the solid structures of the body. They are every now and then experienced in recent wounds, especially deep and narrow wounds made by small-bore rifle or pistol shot, but are more particularly so in chronic wounds in which foreign bodies are suspected to be lodged; wounds in which the original bullet-tracks have become contracted to narrow sinuses, and in which other changes have taken place rendering the directions of these sinuses tortuous or otherwise intricate. The finger may not be able to penetrate the small and constricted passage of such a wound; and the probe, even if it be enabled to traverse it, and happen to reach a hard substance, may fail to give the desired information as to its nature—whether it is striking against bone or the foreign body which is suspected to be lodged.

It may be readily ascertained by striking or rubbing a leaden bullet out of the body with a silver probe, and comparing the peculiar dull sensation conveyed to the fingers with the sensation experienced when a piece of bone is struck or rubbed, that one cannot under such circumstances be deceived with the eyes shut as to the respective differences between the two substances. But when the bullet or piece of bone is at the bottom of a wound, and the probe comes in contact with the side of the wound, especially if this side happen to be bone; or if the walls of the track be fleshy, and, while the probe is in contact with them, its extremity is pressed against bone which has become smooth and eburnated on the surface; or if any soft tissues intervene between the end of the probe and the object impinged upon it; it will be found such a complicated sensation is given to the fingers that the diagnosis is rendered exceedingly difficult and uncertain.

No more remarkable illustration of the difficulty of diagnosis just adverted to could be adduced, perhaps, than was afforded in the instance of the wound received at Mentana by General Garibaldi. In that case, the opening presented to the surgeon beneath the integument consisted of a fissure across the base of the inner malleolus. This fissure was not wide enough to admit a finger; and ordinary probes, when inserted, so failed to give satisfactory evidence on the important question of a foreign body being impacted in bone near the ankle-joint, that some of the ablest surgeons in Europe, after exploring with them, were led to declare that no bullet or foreign body had become lodged in the wound. And this occurred in a case where the opening made by the projectile was not much more, if any more, than an inch in depth, in which the track was not tortuous, nor among tissues of different kinds or of intricate arrangement, as frequently happens in doubtful cases.

M. Nélaton, after his visit to General Garibaldi, was led to think of various devices for determining whether the ball was lodged in the wound or not. His first idea was to obtain a steel probe cut like a file

at one extremity. He presumed that, by passing such an instrument down to the substance which was suspected by some to be the bullet, and by giving it a rotatory motion, sufficient would be brought away on the teeth of the file to determine its nature, whether bone or lead. At the same time that he was having this instrument made, he reverted to the idea of a chemical reagent, which had been tried before in similar cases of doubt, but without success. Acting on this notion, M. Nélaton applied to M. E. Rousseau, the chemist, to furnish him with some ample means of determining the presence of lead in a wound by chemical analysis. M. Rousseau then suggested the introduction of a body capable of bringing away a metallic impression, should metal be present, such as rough porcelain; thus making the metal capable of being recognised not only by chemical reaction, but by all its ordinary characteristic physical signs. This suggestion led to the construction of the instrument which, since its successful application in Garibaldi's case, has become known as Nélaton's probe.

Nélaton's probe consists of a slender rod of metal, five or six inches in length, terminated at one end by a small knob of white, unglazed, biscuit china. The other extremity of the probe is furnished with a small handle, grooved ridge-and-furrow fashion, in order that the finger and thumb may the more easily roll it between them, while the porcelain knob is being pressed at the bottom of the wound against the suspected foreign body. If it be a leaden bullet against which the porcelain is rubbed, a very distinct mark of lead is impressed on the latter, which is not easily obliterated. The bullet itself is thus caused to give ocular demonstration of its presence and place of lodgment. If the foreign body be iron, having a rusty surface, a stain of rust will be found on the china.

The round ball of china which is fitted to the Nélaton test-probes usually has a diameter of rather more than a quarter of an inch. This is often large enough to cause a difficulty in introducing it through the small fistulous tracks among fibrous tissues which are frequently met with as one of the chronic effects of gun-shot wounds. A sinus of this kind, unless connected with necrosed bone, usually leads to suspicion in the mind of the surgeon that it is prevented from becoming completely closed by the lodgment of some foreign body which passed along it at the time of the original wound. It is, therefore, just one of the cases in which such a test-probe offers itself as a valuable diagnostic aid to the surgeon, but where the size of the round china knob too often prevents the attainment of this object. A probe tipped with a piece of the biscuit china of less diameter, and more oval in form, is required for these narrow fistulous tracks. In a recent wound, the larger round ball is more convenient. It is not so likely to be impeded in its passage along the wound, and the impression made by the lead upon it is more obvious to observation.

The porcelain test-probe was much used during the war of the rebellion in the United States, and many favourable reports of the results of its employment have been published. A very ingenious modification of it, but one of doubtful practical utility, was manufactured during the war by the eminent surgical instrument-makers, Messrs. Tieman, of New York. In this instrument, the porcelain is placed at the extremity of a long flexible gum-elastic tube, which takes the place of the metallic stem in the ordinary probe. The length of the whole instrument is thirteen inches, the flexible part being nine inches long. By turning a screw at the handle in different directions, and by means of a mechanical contrivance concealed within the tube, the lower part of the instrument, at the end of which the porcelain is placed, can be caused to turn slowly round to the right or left, at the pleasure of the operator. It may be moved round so as to assume a considerable curve in either direction.

This instrument has obviously been designed with the purpose of applying the porcelain test in cases where the ordinary Nélaton probe cannot be used; more especially along deep and tortuous bullet tracks, whose ultimate direction is either uncertain or known to be turned from a straight course. The operator is supposed to cause the porcelain to search for the foreign body, as well as to identify it when found by bringing to light the usual evidence of its presence. I have only tried the instrument on the dead body, but the experiments have not been attended with favourable results. The chief sources of failure with it were found to be, firstly, the uncertainty concerning the direction taken by the end of the instrument when turned in search of the bullet among yielding tissues, at distances far removed from the aperture of entrance and from sight; and, secondly, the difficulty of applying sufficient force to get a metallic impression, even when the point of the instrument was directed against the foreign body, owing to the flexibility of the long tube at the end of which the button of china is placed. Another difficulty experienced was the following. If the china knob became entangled in the tissues at the end of a long track, or was prevented from moving freely by any cause, then the screw, not being able to act on

the extremity, caused the middle flexible portion of the instrument to become curved, so as to press on one side the soft tissues of the track of the wound, along which the probe had been passed. It was only through the displacement of the soft tissues being visible externally after it had occurred to some considerable extent, that a knowledge was gained of the fact that the porcelain end was not moving in obedience to the screw, but only that part of the probe lying in the track of the bullet.

It is evident, from the nature of the porcelain test-probes just described, that direct and firm contact between the porcelain and a bullet is essential, in order that the former may furnish the evidence which the surgeon requires. If it be merely a little blood, serum, or soft coagulum, in front of the bullet, pressure by Nélaton's probe will squeeze it away, and the leaden mark can be obtained; but if any resisting medium, however thin—the thinnest membrane, for example—happen to be placed between the surfaces of the metal and the china, no impression will be made on the latter. And there are various substances which are liable to be so interposed—such as muscular or cellular tissue pushed by the knob of porcelain itself before it; pieces of linen, cloth, paper, or other substances which have entered with the bullet; a piece or edge of bone projecting in front of it, and other such matters. The evil in such occurrences may not simply be the impediment to obtaining an impression from the lodged bullet; but possibly a surgeon may be led to an erroneous conclusion that he has obtained proof of no foreign body being lodged, because the usual evidence of its lodgment is absent from the porcelain. This may lead to delay in the healing process and protracted suffering to the patient, which might have been avoided had a more correct diagnosis been arrived at.

[To be continued.]

## CASE OF FRACTURE OF THE ATLAS FROM GUNSHOT INJURY.

By WILLIAM STOKES,  
Surgeon to the Richmond Hospital, Dublin.

IN the following brief narrative of the case of the late Constable Talbot, I am indebted to Mr. Agmon Vesey and Mr. J. Walker for a record of many particulars connected with the case, which were noted by these gentlemen, who had the best opportunity of accurately recording them, in consequence of the unremitting attendance they bestowed on the patient, from the time of his admission into hospital up to the period of his death.

Thomas Talbot, aged 44, a large powerfully built muscular man, was admitted into the Richmond Hospital on Wednesday morning, July 12th, 1871, between 12 and 1.0 A.M., suffering from a gunshot-wound of the neck, which he had received about an hour previously to his admission. He was helped into the out-patient room of the hospital by Inspector Gorman and another constable, and immediately afterwards was seen by Mr. Vesey. The patient seemed weak; and, blankets being laid on the table, he was placed on it in the horizontal position. There had been some bleeding from the wound at the station-house in Green Street; but the amount of blood lost was inconsiderable, and at the time of his admission into hospital the hæmorrhage had completely ceased. The patient was perfectly conscious, spoke clearly and distinctly, but was greatly depressed in spirits, and even then despaired of his ultimate recovery. The temperature of the body was normal, with the exception of the feet, and to these a hot jar was applied. Immediately after this, at the patient's request, the surgeon who was on accident duty that day, Mr. Hamilton, was sent for; but as he happened not to be in town, Mr. Walker, who went for him, called for me. I accordingly went, and arrived at the hospital at 2.45 A.M. On my arrival, I found the room where the patient lay filled with people, chiefly police. On the room being to a certain extent cleared from the large and inconvenient crowd that had collected, I proceeded to examine the patient. He spoke slowly, but in a firm and distinct voice, and mentioned that he did not feel at that moment any violent or acute pain. On examining the wound, which I found behind the left ear, a little posterior to the mastoid portion of the temporal bone, I perceived a small round opening about the size of a fourpenny-piece, through which there was not at that time any sign of even an oozing of blood. His respiration was at this time tranquil, and the heart's action regular and strong. Under these circumstances, I considered it advisable to ascertain the position of the foreign body; and, having regard to the situation of the wound, if possible, to remove it. The

patient also expressed an anxious desire than an attempt should at once be made to extract the foreign body. Taking, therefore, a silver probe, I passed it gently into the wound, and found that it took a direction from behind, downwards, forwards, and inwards. After passing in this direction for nearly an inch, the end of the probe struck on something hard; and, on depressing the handle of the probe somewhat more, and striking again, I felt quite satisfied that there was a difference between the body first struck and that on which the probe now rested—the first being, in my opinion, metal, the second bone. As the former was apparently within easy reach, I considered it desirable to make an attempt to remove it, before there was time for any inflammatory action to supervene. Accordingly, I slightly enlarged the opening, cutting horizontally from before backwards; and, through the opening thus enlarged, I passed a fine forceps down, apparently to the bottom of the wound, and endeavoured to lay hold of the ball. This attempt, however, was not attended with success. I then introduced another and still smaller forceps; and, on making a third attempt and not succeeding, I determined to abandon for the time any further proceeding to remove the foreign body, and to wait until I had better light, and also the advice and assistance of my colleagues.

At 11 A.M. on the same day I again saw Talbot, in consultation with Mr. Hamilton, Dr. R. W. Smith, Mr. Tufnell, and some other medical gentlemen unconnected with the hospital. I stated what had already been done; and it was agreed to examine the wound again. This was done in the first instance with an ordinary silver probe; and the existence of a metallic body, apparently in the situation of the lambdoid suture, was determined. Subsequently, a Nélaton's probe was used, but the instrument on this occasion proved neither "reliable" nor "infallible", as some persons have of late inaptly termed it.\* It was then determined to make a second attempt to remove the foreign body. Mr. Hamilton stated that he could not quite satisfy himself that the hard body which the probe struck was metallic; but he thought that the operation should be performed for the likelihood of finding the ball, and that the wound should be enlarged in order to relieve the tension of the adjacent soft structures, and to give a free exit to the suppuration which would inevitably follow the gunshot injury. It was accordingly determined that the patient should be brought into the theatre of the hospital, as the light was much better there. During the operation I was assisted by Mr. Hamilton, Dr. R. W. Smith, Mr. Tufnell, Mr. Vesey, Mr. Walker, and Dr. Robert McDonnell. At Talbot's own request, chloroform was not administered; and during the operation he was never heard to utter a murmur. What was done was simply to enlarge the wound, cutting with a small scalpel horizontally from before backwards. In doing this, two arteries were severed: one was a very small vessel, which was at once secured by a ligature; the other was a larger one, and was either the occipital artery, or a large muscular branch which it often gives off in this situation. There was no strong jet of blood from it; but it was obvious that a considerable

vessel had been divided, from the rapid manner in which the wound filled up with blood. After sponging out the wound, Mr. Hamilton made pressure with the index finger of his right hand against the temporal bone, and in this way hæmorrhage was promptly arrested. I then commenced to search for the ball, and in doing so used two or three different kinds of forceps. However, although I was satisfied that there was a metallic body in the wound—an opinion in which Mr. Tufnell and others fully concurred, and which the *post mortem* examination verified—still, at the operation, it soon became obvious to me and to those who were assisting, that it was useless to proceed further in attempting to extract it. Consequently I felt reluctantly obliged, though knowing how very important it is to remove, if possible, foreign bodies when lodged in this situation especially, to desist from all further attempts to extract the ball.† Mr. Hamilton then, at my request, removed his finger, and I then, without difficulty, seized the vessel and secured it with a silken ligature. To prevent the possibility of the ligature slipping off, I left the point of the tenaculum in the vessel on the distal side of the ligature. It is my firm conviction that, during the operation, at the very outside not more than six or seven ounces of blood were lost altogether. I may mention that this belief is also shared by Dr. R. W. Smith, Mr. Hamilton, Mr. Tufnell, Mr. Vesey, and Mr. Walker. To a person of Talbot's great strength and muscular development, such a loss of blood could not by any possibility have been of the slightest moment. On the operation being concluded, water-dressings and a bandage were applied, and the patient was soon afterwards removed to bed. At 4 o'clock P.M. I again saw Talbot, in consultation with my colleague, Dr. R. Adams, who was unavoidably absent from the hospital at the time of the operation. When we went into the ward we found that Talbot's depositions were being taken by the legal authorities. Talbot was not unnaturally somewhat agitated, and he presented three remarkable conditions, which I had not observed at all in the morning: these were an almost complete fixation and retraction of the head, a remarkably tremulous condition of the tongue, and a cold clammy perspiration over his hands.

July 13. At 10 A.M., I saw the patient and found that he had had a restless night, but had got some sleep. He was free from pain, and was quite sensible. There had been no hæmorrhage, and, on the whole, he appeared to be doing well. He was ordered beef-tea, wine, and anodyne draughts containing camphor and solution of muriate of morphia. At 10.15 P.M., his pulse was very quick. He was in some pain, but was inclined to sleep, and was quite sensible. He had pain in the forehead during the day.

July 14, 10 A.M. Pulse 120. He had been very restless. Mr. Walker saw him frequently during the night, and stated that at 3 A.M. he had a severe rigor, followed by profuse sweating. This was also accompanied by great pain in the forehead and neck. By Mr. Vesey's advice, he got a warm stimulating draught, with opium. He had five attacks of rigor between 3 A.M. and 6 A.M. At this latter hour he first got some sleep. After a full consultation of the surgeons of the hospital, it was determined to remove the tenaculum, which I accordingly did without any difficulty. His bowels being confined, he was ordered some opening medicine. The head was still fixed and retracted.

July 15, 10.15 A.M. Pulse 120. The patient had had five or six hours' sleep. There was some discharge from the wound. A linseed-meal-poultice was ordered to be applied over the wound. Towards evening, at about 8 P.M., Talbot got into a very unusual and excited state, said he knew that he would soon die, and insisted on having his brother telegraphed for. Pulse very quick; tongue still tremulous. His whole body was covered with a cold clammy sweat.

July 16. He had a very restless night; no sleep. He did not complain of pain. He was bathed in profuse sweat, and in a very excited state. At about 6 A.M., Talbot's brother observed that there was bleeding from the wound. He pressed a handkerchief against the wound, and immediately afterwards Mr. Walker, and subsequently Mr. Vesey, arrived. They found him pressing on the wound. A large clot of blood was observed on the pillow. Mr. Vesey did not raise the head, but turned it a little to one side, removed part of the dressing, and found a slight oozing of blood. A fresh compress and bandage were applied, which effectually arrested all further hæmorrhage. The patient was observed to be covered with a cold clammy sweat. At about 11 A.M. I saw Talbot. I observed a great change for the worse. His eyes were staring and expressionless. He was in a very agitated and excitable state. His pulse had risen to 140, and he was slightly delirious. Many of the answers he gave were unconnected with the questions that were put. At this time he was seen along with me by Sir William Wilde and Mr. Porter. Shortly after this his symptoms became much more urgent. His pulse rose to 160; his breathing more hurried; then he became violently delirious, requiring several persons to keep him in his bed. He refused all food, medicines, stimulants, etc. His

\* In connection with the Nélaton probe, I may mention that Professor Longmore, undoubtedly one of the highest living authorities on military surgery, is of opinion that the instrument is only of value when its evidence is positive. He observes, in a letter recently received: "It settles the question of lead or rusty iron lodging when it brings away the markings; but it settles nothing when it does not bring away any marks. A surgeon would be very unwise if he concluded no foreign body to be present because he got no evidence of its being present on using the Nélaton probe." In a most important letter also on the subject of the Nélaton probe, which recently appeared in the *Times*, which was signed "An Army Surgeon", the following passage occurs: "I have in several instances failed to obtain indications of the presence of bullets and fragments of lead in wounds by Nélaton's probe, when I have determined their presence by other instruments. It would be entering too much into technical matters to describe these instruments, or to discuss the subject of extraction of bullets, in the columns of the *Times*; but a man does not require to be a surgeon to understand the action of Nélaton's probe, and the extent of reliance which may be placed on it. Nélaton's probe essentially consists of a small knob of 'biscuit china' placed at the end of a slender metal stem. Just as we write on a porcelain tablet with a lead pencil, so the china knob takes an impression of a leaden bullet or of a rusty iron projectile when it is pressed fairly and directly against it; but just as we cannot write on a porcelain tablet if a piece of chamois leather, paper, or other substance happen to be between the tablet and the pencil, so the china knob will fail to indicate the presence of a bullet when a piece of skin, wadding, muscle, or other substance, lies between it and the projectile. Again, if the bullet have sunk in bone, or a portion detached from it has sunk in a cleft of bone, and if the probe happen to be pressed only against the edge or edges of the bone, no indication will be conveyed by it. It is evident, therefore, that on many occasions the test by Nélaton's probe is anything but conclusive, and that if a surgeon were to decide that no metallic substance is present in a gun-shot wound, because he could find no indication of it from the use of Nélaton's probe, he might be led into serious error."

† In a communication recently received by my friend Mr. Tufnell from Professor Longmore on the Talbot case, the following passage occurs. "It would have been acting wrongly, had every effort not been made to extract the bullet from the situation in which it was supposed and reasonably inferred to be lodging. It is of immense importance that foreign bodies lodging in the walls of cavities, whether abdomen, chest, cranium, or spine, should be got away, if possible. No one acquainted with such subjects—at least, no one who respects truth more than some other ulterior object—can really believe that the man's death in this case was due to anything else but the direct effects of the gun-shot wound which had been inflicted upon him."

pupils began to dilate, then to contract, and then to dilate enormously again. The respiration became stertorous, then "blowing", and subsequently diaphragmatic. The violence of his struggles surpassed anything I have ever seen even in cases of the most violent delirium; and his screams were very loud. At about 2 P.M. he began to become much worse, and it became obvious that his end was approaching. After each attempt to get off his bed he became weaker. At 3 P.M. he was seen again by me, Mr. Adams, Mr. Hamilton, Sir W. Wilde, and Mr. Porter. Shortly after this he became comatose; and at about 4 o'clock on the evening of that day he died.

July 17th. At about 1 P.M. I proceeded to make a *post mortem* examination. There were present Mr. Tufnell, Dr. Yeo, Dr. Kirkpatrick, Mr. Vesey, Mr. Walker, Mr. Woodhouse, Mr. Smith, Mr. Frazer, Mr. Johnson, Mr. Elliot, Mr. Goode, and two or three others. Mr. Vesey, who acted under my directions, began by removing the scalp and sawing off the calvaria. The brain was then removed and inspected. Its coverings at the posterior and lateral regions (especially at the left side) were found intensely congested. There was a great deal of subarachnoid effusion on the left side also; but there was no evidence of any purulent matter either on or beneath the meninges. On cutting into the substance of the brain, nothing abnormal was observed. An incision was next made down on the original wound, and a portion of the bullet was discovered firmly wedged in the suture between the temporal and occipital bones. Following the incision a little deeper, a collection of matter was discovered in the immediate vicinity of the atlas; and above the left transverse process of the atlas two pieces of lead were found. A third piece of lead was also found lying a little external to the left condyle of the occipital bone. On examining the occipito-atloid articulation, a quantity of purulent matter was found communicating with the spinal canal. The membranes of the cord, from the base of the brain down to the third cervical vertebra, were in a state of inflammation; and it is no exaggeration to say they were bathed in pus. The cord was greatly inflamed and abnormally soft. A fracture of the atlas was next discovered, whereby a small portion of the posterior part of the left superior articular facet was broken off. Several very minute fragments of bone were subsequently found in the adjacent tissues; so that the portion of bone broken from the atlas may be said to have been pulverised. A careful search was then made for the remaining portions of the bullet, but I did not succeed in finding them. Probably, had we continued the search much further, we should have succeeded; but the sole object I had in view in making the examination was, not to discover the whereabouts of some missing fragments of a very minute conical revolver-bullet, such as No. 7 Eley is, but to determine what was the immediate cause of Talbot's death; and, having determined that to my satisfaction and that of all who were assisting, I did not deem it necessary to continue the dissection further, especially as Talbot left distinct and specific directions that nothing but the head and the neck at the situation of the wound were to be examined. A part of the skull, comprising the portions of the temporal and occipital bones in which a portion of the bullet was wedged, was removed; also the atlas and axis. General decomposition of the body had progressed very rapidly.

From the results of the *post mortem* examination, my belief as to the immediate cause of Talbot's death is, that the fracture of the left superior articular process of the atlas necessitated the tearing of the posterior occipito-atloid ligament, and that thus a communication was established between the parts external to the spinal column, where the abscess probably originated, and the spinal canal, through the vertebral canal, or canal for the passage of the vertebral artery; that the fragments of the bullet and the minute particles of bone found in the soft tissues immediately adjoining the fracture, and the tearing of the ligamentous structures between the occiput and the atlas, gave rise to the formation of an abscess, which abscess penetrated the articulation between the atlas and the occiput; that the matter also penetrated into the spinal canal through the vertebral canal; that the existence of that suppuration gave rise to inflammation of the coverings of the spinal cord; that the inflammation extended to the cord itself; and that the inflammation of the coverings of the cord extended up to the base of the brain—these inflammations being the immediate cause of death.

I have, in conclusion, to acknowledge with gratitude the recent publication in the *Times* of the memorandum signed by Sir James Paget and the other justly celebrated English surgeons, who, unsolicited and with characteristic generosity, came forward and stated their opinion not only as to the inevitably fatal nature of the gun-shot injury which Talbot received, but also as regards the treatment that was adopted in his case in the Richmond Hospital.

## EXTRACT FROM A LECTURE ON DISLOCATION OF THE HIP-JOINT: DR. BIGELOW'S VIEWS.

By JONATHAN HUTCHINSON, F.R.C.S.,  
Senior Surgeon to the London Hospital, and Lecturer on Surgery, etc.

NEXT, gentlemen, let me say that I regard the researches of Dr. Bigelow in respect to our subject as amongst the most valuable of recent additions to the science of surgery. His essay on the *Mechanism of Dislocation and Fracture of the Hip* I recommend to you most strongly, as an excellent example of experimental investigation applied to a subject concerning which but too many had been contented merely to guess and speculate. I will endeavour to state to you briefly some of the chief results of the Boston professor's work—for details, of course, I must refer you to his book.

The main fact to which I must ask your close attention is, that the ilio-femoral ligament is the strongest part of the envelopes of the joint; that it is very rarely torn through; and that it is to it that the peculiar positions of the bone in the several displacements are chiefly due. This ligament must be described as arising from the anterior inferior spine of the ilium, passing downwards and outwards, and being inserted into the whole length of the anterior intertrochanteric line. Thus at its origin it is not more than half an inch broad, and at its insertion more than two inches. It is supplementary to the capsular ligament, over which it passes, and with which it is inseparably connected. You will find in most anatomical works that the term ilio-femoral or "accessory intertrochanteric ligament" is restricted to the lower part of the structure described; but as the whole arises from one part, there can, I think, be no question that it is well to regard it in its entirety. Dr. Bigelow purposes for it the name of the Y-ligament, because its lower fan-shaped expansion has a space between its upper and lower portions like that between the arms of an inverted Y. The accompanying diagram, copied from his work, well illustrates the arrangement referred to (Fig. 1). For

Fig. 1.—The Y-ligament, shewing its inner and outer bands: the former known as the ilio-femoral. (Copied from Bigelow's work, page 18.)

myself, I doubt much whether anything is gained by rechristening it. However, whatever name we give it, the truth remains the same, that it is this ligament—as strong as the ligamentum patellæ or the tendo Achillis—which in dislocations restrains the movements of the great trochanter, and thus regulates the position of the limb. It is this ligament which, when we reduce by manipulation, guides the movements of the bone. We have long known that the ligamentum teres has nothing to do with these matters, being indeed powerless to keep the

bone in the socket; and we may now, I think, discard, to a large extent, the supposed influence of muscles.

The diagram which I now show will illustrate the action of the Y-ligament in the common form of dorsal or posterior dislocations (Fig 2).

Fig. 2.—Dislocation upon the dorsum, shewing the influence of the Y-ligament in causing inversion. (Copied from Bigelow's work, page 40.)

It there holds the great trochanter to the pelvis, and thus inverts the limb. It also, assisted by other lower fibres of the capsular, hinders the passage of the head of the bone upwards, and thus keeps the shortening within limits. Upon it, as upon a pivot, the neck of the bone will move, if you commence manipulations and use the shaft as a lever. It will be by its aid, and not, as erroneously supposed, by that of the adductor muscles, that the head will be directed into the socket if you flex and then abduct (or, still better, circumduct outwards), as in our usual method of reduction.

Amongst the special services which Dr. Bigelow has done, is that of explaining the peculiarity of "the dislocations into the ischiatic notch," and of teaching us how to reduce them. His assertion is, that they differ very little from the majority of so-called dorsal dislocations, for in both the head of the bone lies not so much on the dorsum illi as just behind, or behind and above, the acetabulum; and in neither does it really pass so far back as the sciatic notch. The real difference between the two consists in the relation of the head and neck of the bone to the tendon of the internal obturator muscle and to the portion of capsular ligament beneath it, these being below the neck in a true dorsal, and above it in the so-called ischiatic dislocation. This fully explains the increased difficulty in reducing the latter dislocations by the old method, and also the ease with which the flexion plan succeeds.

Dr. Bigelow believes that the greater or less laceration of the capsular ligament is a matter of very little consequence to the patient's chance of good recovery; and he instructs us how, in cases when the smallness of the hole in this structure is supposed to be the impediment to reduction, we can easily and safely tear it as much as we wish.

It is not my intention to bring before you in detail at the present time the important statements made by the author I am quoting respecting the other special forms of dislocation. These may be better reserved until we have an opportunity for demonstrating the dislocations on the dead body. It will be sufficient at present to say that they seem to me to simplify greatly a very difficult subject, and that I have no doubt that they will speedily bear good fruit at the bedside. What I chiefly wish you to recollect is, that it is the strong ilio-femoral ligament which, in the backward or dorsal dislocations, holds the great trochanter forwards and inverts the limb, which in the dislocations downwards, still holding the trochanter, flexes the limb, and in dislocations of the head of the bone inwards (thyroid), still restraining the movements of the great trochanter, everts the limb. All these results can be easily witnessed by experiment in the dead body. Lastly, in some rare cases in which the displacement follows no rule, the explanation is to be sought in the fact that this ligament has been wholly or partially torn through. It is, however, very strong, and its rupture is very infrequent.

I need scarcely add that Dr. Bigelow is of course a warm advocate

of the manipulation, or flexion, method of reduction. He urges that almost anything may be done if you only recollect the manner in which the ilio-femoral ligament will be stretched in the different positions of the bone. Extension horizontally, whether in a straight line or obliquely, he for the most part opposes strongly, as only likely to be successful after forcibly tearing the important structure referred to. Extension with the thigh bent at right angles to the pelvis he as warmly advocates, for in this position the ligament is relaxed. For the accomplishment of this he has devised a special apparatus, which looks likely to

Fig. 3.—Tripod for angular extension. The pelvis is buckled to the floor. The flexed leg is suspended by pulleys from the apex of the tripod. A bar fixed to the splints, and, crossing the knee transversely, serves to rotate the limb.

be very useful (Fig. 3). As a practical suggestion likely to be available under the frequent conditions when this triangle may not be at hand, he advises that the surgeon should place his foot (unbooted) on the patient's pelvis, and then lift from the knee.

#### TEMPERATURE IN A CASE OF FRACTURE OF THE SIXTH CERVICAL VERTEBRA.

I ENCLOSE a short report of a case of fracture of the sixth cervical vertebra. It was caused by direct violence, which detached the spinous process and laminae, and, as was found on *post mortem* examination, crushed the pedicles and transverse processes into small pieces. There was complete paralysis of all parts below his arms; these latter were unsteady, and had cramps and abnormal sensations. Respiration was purely diaphragmatic. There were retention of urine and loss of control over the sphincter ani. The patient lived five days, and suffered most from thirst. The temperature was taken twice daily, at 10.30 A.M. and 8 P.M., in the mouth and on the thigh. The chief interest of the case lies in the concomitant variations till near death. The fall in the temperature of the mouth in the last observation might be due to the patient's sucking ice freely during the last few hours of life.

	Temperature of		Pulse.	Respiration.
	Mouth.	Thigh.		
First evening .....	97	...	60	23
Second morning .....	96	99.4	88	17
Second evening .....	96.8	100	85	17
Third morning .....	99	102.4	81	25
Third evening .....	99	103	91	16
Fourth morning .....	99.6	102.4	92	20
Fourth evening .....	98.2	101.8	92	16
Fifth morning .....	100.6	104.8	116	21
Fifth evening .....	99.8	106.2	122	29

I am not aware of any report similar to the above having been published.  
GEO. H. SAVAGE, M.D.Lond.

## THE DIAGNOSIS OF ANEURISM OF THE AORTA BY THE AID OF THE LARYNGOSCOPE.

By GEORGE JOHNSON, M.D., F.R.C.P.,

Physician to King's College Hospital; Professor of Medicine in King's College.

It is well known that, in cases of aneurism of the arch of the aorta, symptoms referable to the air-passages not unfrequently arise. The diagnosis of these cases is often much facilitated by the use of the laryngoscope. Such a case I saw lately with my friend and former pupil, Dr. Richards; the patient being under the joint care of Drs. Butler and Richards, of Winchester.

A gentleman, Mr. H., aged 33, had noticed occasionally for a year past that, after running hard, his breathing became short, and attended with a noise in the throat. About six weeks before I saw him, while running after a wounded hare, his breathing became so difficult that he could run no longer, and he was nearly suffocated. At the time of his visit to me, on the 30th October, the chief symptoms were cough, stridulous breathing, and occasional difficulty of swallowing. The voice was clear and loud; and I remarked to Dr. Richards, before looking into the larynx, that, if the obstruction which caused the stridor were in the larynx, there would almost of necessity be more or less hoarseness and feebleness of voice. A laryngoscopic examination showed the larynx healthy, except slight congestion and redness of the mucous membrane; and while he drew a deep inspiration through a widely open glottis, as seen in the mirror, we heard loud stridor, evidently originating below the larynx. Then the question arose, Is there an aneurism pressing on the trachea? No unusual pulsation could be felt anywhere. No abnormal sound was heard over the front of the chest; but, on auscultation over the upper dorsal spinous processes, the tracheal stridor was heard there almost as plainly as when the stethoscope was placed over the front of the trachea itself; and the voice in that situation had a loud bronchophonic character. In addition to these physical signs, the respiratory murmur was decidedly more feeble over the right than over the left lung. We came to the conclusion that an aneurism of the transverse aorta, pressing on the trachea, and narrowing the tube, was the cause of the stridor, the occasional dyspnoea, and the dysphagia.

I did not see the patient again; but I learn from Dr. Richards that he became steadily worse for some time, and rapidly so a few days before his death, which occurred exactly three weeks after his visit to me. The difficulty of breathing progressively increased, until it became a constant struggle; there was occasional dysphagia; and he died from apnoea on the 20th November. Dr. Richards has kindly sent me notes of the examination made twenty-four hours after death, and a photograph of the aneurism, which I have had copied upon wood.

At the back of the transverse aorta there was a shallow pouch an inch and a half in diameter; at the upper part of this pouch an oval opening, with smooth rounded margins, and scarcely large enough to admit the tip of the little finger, communicated with an aneurism about the size of a walnut; this tumour pressed backwards on the trachea

just above its bifurcation; the cartilages were eroded; and the posterior wall of the aneurism was mainly composed of mucous membrane, which over the most prominent part of the tumour had an ulcerated opening a quarter of an inch in diameter, so that a clot of fibrine alone inter-

vened between the blood in the aneurism and the air in the trachea. The canal of the trachea was nearly filled by the aneurismal tumour, which, as may be seen in the woodcut, projects more over the right than over the left bronchus, and so explains the comparative feebleness of the respiratory murmur over the right lung. The recurrent nerves were found to have no connexion with the tumour.

The case whose history I have here briefly given, is a type of a class of cases. A similar case is at present under my care in the hospital. The chief features of these cases are, that an aneurism at the back of the transverse aorta presses on the trachea, narrows the canal, and so causes frequent loud cough, dyspnoea, and stridor; the stridor is tracheal, not laryngeal; while the voice remains clear and loud, and the laryngoscope shows the larynx quite normal, or the mucous membrane only slightly congested. The tracheal stridor and the sound of the voice are distinctly heard over the upper dorsal spinous processes, in consequence of the trachea near its bifurcation being pressed backwards against the bodies of the vertebrae, so that the sound is conducted through the bones. The symptoms in these cases may steadily or rapidly grow worse, but are not liable to sudden paroxysmal increase, except after unusual exertion, by which the aneurism becomes distended, and so the pressure on the trachea is temporarily increased.

There is another distinct class of cases in which laryngeal symptoms result from pressure of an aneurism on the pneumogastric nerve or its recurrent branch, the muscles of the larynx being either paralysed or thrown into a state of spasm. I have published a case of this kind in the fifteenth volume of the *Pathological Transactions*, p. 72. In that case, the symptoms bore a striking resemblance to those of laryngitis. It is not only of scientific interest, but also practically important, to distinguish the two classes of cases; and the laryngoscope affords much assistance in the diagnosis. When pressure on the nerves causes spasm or palsy of the laryngeal muscles, the voice is usually feeble and husky. With laryngeal spasm, there will be stridulous breathing, which may come and go quite suddenly, often without obvious external exciting cause, like paroxysms of infantile laryngismus stridulus. In these cases, the stridor is laryngeal, not tracheal. Inspection with the mirror during the paroxysm of spasm shows closure or great narrowing of the glottis, without structural change within the larynx, as in cases of hysterical laryngismus. When the spasm relaxes, the larynx appears quite normal. When pressure on one recurrent nerve has caused unilateral palsy of the laryngeal muscles, one arytenoid cartilage, with its vocal cord, may be seen to remain motionless when vocalisation is attempted; and the voice is feeble and husky. In these cases, the tubular breathing and bronchophony resulting from pressure of the trachea against the vertebrae are absent. Now the chief practical advantage of a correct diagnosis between stridor and dyspnoea the result of direct pressure on the trachea, and stridor from laryngeal spasm, or palsy, the result of pressure of an aneurism on a nerve, is this, that, in the latter class of cases, temporary relief may be afforded, and life prolonged, by tracheotomy; whereas in the former class tracheotomy is obviously quite useless, since the obstruction is below the point where the trachea can be opened. When laryngeal symptoms result from spasm, repeated doses of chloral have a decided influence in lessening the spasmodic tendency. Chloroform inhalation, also, relaxes laryngeal spasm, and therefore it may sometimes be employed as one means of distinguishing spasm of the larynx from a more permanent obstruction in the larynx or trachea.

## THE SYNTHESIS OF ACUTE RHEUMATISM.\*

By BALTHAZAR W. FOSTER, M.D., M.R.C.P. Lond.,

Professor of Medicine in Queen's College, and Physician to the General Hospital, Birmingham.

THE lactic acid theory of acute rheumatism has of late somewhat declined in popularity. The arguments of Prout, the experiments of Richardson, and the statistics of the alkaline treatment, have all failed to establish it firmly. Like many other theories resting on surer grounds, it has suffered from the scepticism of the day. The mint water treatment and other similar manifestations of nihilism have served, more or less, to strengthen the bias in favour of doubt, and to increase the number of sceptics. For some years past, I was myself a disbeliever in the lactic acid theory; and it is to lay before the profession the facts which have recently recalled me to my allegiance that this paper is published. These facts, when added to the arguments which have been adduced by many previous writers, and to the experimental proofs which we already possess, will, in my opinion, strengthen

\* Read before the Birmingham and Midland Counties Branch.

the evidence which points to lactic acid as the poison of rheumatic fever.

In the *BRITISH MEDICAL JOURNAL* of February 25th, 1871, I read with much interest an account of Dr. Cantani's observations on the lactic acid treatment of diabetes. At that time, I was engaged in completing an inquiry into the effects of different drugs on the sugar-excretion in diabetes. I determined to add one more drug to my list, and to complete my research by observing the effects of lactic acid.

A man (Wright) who had just come into the General Hospital under my care, suffering from diabetes, offered me the opportunity. His age was 31, and he had been ill some four months before his admission. By trade he was an iron-caster, and up to this attack of illness he had been a healthy man, and had never suffered from rheumatism. He was married, and had several strong, healthy children. On a mixed diet, he passed during the first week of his stay in hospital an average of 180 ounces of urine daily, containing 49 grains of sugar in the ounce. On a strictly animal diet, continued two weeks, the sugar fell to an average of 36 grains an ounce, and the urine passed to an average of 116 ounces daily. The skin was dry and branny. The sugar-excretion remained pretty stationary on strict diet, but lung-symptoms began to manifest themselves, and steadily increased.

On March 8th, I ordered the patient fifteen-minim doses of lactic acid dissolved in an ounce of water four times a day. The dose was doubled the next morning, and in the afternoon he complained of acute pains in his joints, and flying pains about his limbs. In the evening, as these pains had increased, the medicine was discontinued by order of the resident medical assistant.

On March 10th, no lactic acid mixture was taken, and the pains gradually ceased.

On March 11th, I saw the case; and, regarding the occurrence of the joint-pains as a mere coincidence, repeated the lactic acid in fifteen-minim doses three times a day. On the evening of the 12th, he again felt pains in his joints; and on the morning of the 13th, "the small joints of the fingers of both hands, the wrists, and, in a less degree, the elbows," were noted by the resident medical assistant, Mr. E. A. Elkington, to have become "red, swollen, and painful." On my visit, I was much struck by the appearance of these joints, which were typical specimens of acute rheumatic arthritis. In the evening, both wrists, the small joints of the fingers, and the elbows were all red, hot, swollen, tender, and painful. The heart-sounds were clear. The temperature in the morning was 100; in the evening, 101 Fahr. He had moderate perspiration. Pulse 90, soft and full. The joints were wrapped in cotton-wool, and the lactic acid was discontinued.

On March 14th, in the morning, there was a decided improvement in all the joints; the swelling had much diminished, but heat and pain were still present. Temperature 100; pulse 84. In the evening, all the small joints of the fingers were much better. The wrists were still affected, and he complained of a good deal of pain in the knees, which had hitherto escaped. The heart-sounds were clear. Pulse 90. Temperature 100.8.

On March 15th, the joints were better. The temperature in the morning was 98.6; in the evening, 99.4.

On March 16th, he said that his arms were quite well; his legs nearly so. He had slept much better.

On March 17th, all pains in the joints were gone. Temperature 98.2. Pulse 72.

During the next twelve days, no lactic acid was administered. The case was put clearly to the man, and, as he had felt benefit from the acid mixture and had passed less urine during its use, he elected to run the risk of acute rheumatism. Accordingly, on March 29th, I prescribed seventy-five minims of lactic acid dissolved in twenty ounces of water. This was to be taken as a drink in the course of the twenty-four hours. During the next five days, no rheumatic symptoms appeared. The pulse rose twelve beats on and after the third day; the temperature, which had been previously elevated by the lung-complications, showed no marked change, but on the fourth and fifth days remained steadily at 99°, instead of varying, as it had done for some time previously. On the morning of the sixth day (April 4th), he complained of having had a bad night from joint-pains, which had disturbed him very much, and which came on suddenly after midnight. On examination, the metacarpo-phalangeal and first phalangeal articulations of the first and second fingers of each hand were found to be red, swollen, hot, and painful; the slightest movement aggravated the pain, and he could not on this account pick up anything with his fingers. The pulse was 102. The temperature, which on the previous evening had been 98.2, had risen to 99.4. The heart-sounds were clear. The acid mixture was stopped, and in the evening the pain in the knuckles was less, and the redness had diminished; they were, however, still stiff. No other joints were affected. Temperature 99.2.

April 5th.—His hands were much better, and, of his own accord, he resumed his lactic acid drink, and took about thirty minims of acid in the course of the forenoon. In the evening, the pains had returned in the knuckles, which were swollen, red, and tender. He discontinued the acid, had a fair night, and on the morning of the 6th, found his hands free from pain. He again resumed the lactic acid, and took up to 4 P.M. the remainder of the bottle, containing about forty-five minims of acid. In the evening, at 9 P.M., the pain and swelling had returned in his knuckles, and his left wrist was also affected. He now gave up the acid for two days, and the joint-symptoms gradually disappeared.

The acid drink was resumed on the 9th, and continued to the 13th, but he only took about thirty-five minims of acid a day. He experienced no inconvenience, except flying pains about his joints, till the night of April 13th, when he was disturbed by severe pain in the right wrist, which was found in the morning to be red, swollen, painful, and hot, and was a typical specimen of a rheumatic joint. Pulse 98, full and soft. There was copious perspiration, of acid reaction. The heart-sounds were clear. The elbows and knees became painful and stiff the next day. The joints were all wrapped in cotton-wool as before; and in the course of four days nothing remained except a little stiffness in the right wrist. After a week's interval, the acid was again taken, with like results.

The man now had gained so much experience as to the first indications of a coming attack in his joints, that he was allowed discretionary power as to the time and manner of taking the mixture. By trying it first in small doses, so as not to take more than twenty minims of acid a day, and stopping it for a day or so whenever the joints threatened, he managed to continue the acid for some weeks. Gradually he increased the dose, as advised, and early in June was able to take from forty to fifty minims daily. During this month, he had two sharp attacks of rheumatism in the hands and wrists. By the end of June he was taking seventy-five minims of acid daily; and on July 6th, this was increased to 100 minims. On the 7th, he began to experience considerable pain and stiffness in his joints, and kept his bed (he had been up daily previously) on account of the pain caused by walking. On the 8th, these symptoms were worse, and in the evening his wrists and elbows were very stiff and painful, but the knees were less so. The temperature had risen to 100.6. The acid was stopped. On the next morning, he was better. Temperature 99. The joints were less painful and stiff; there was no redness and no swelling. On the 10th, he again took the acid, his joints feeling much better, and the temperature being only 98.4. In the course of the day, he took 100 minims of the acid; and by the evening the pains had returned in his wrists, elbows, and knees. Temperature 100.6; pulse 100, full and soft; skin moist and perspiring. On the morning of the 11th, his right wrist was red and swollen; the left less so. The knuckles of his right hand were also red, swollen, and painful. His left knee was red, swollen, and very painful and tender. He complained also of pain in the left side, but the heart-sounds were found to be clear; pulse 88; skin still moist. The mixture, which had been stopped on the previous night, was discontinued till July 17th, by which date all the rheumatic symptoms had subsided. After this the man only remained in hospital seventeen days. During this period, he, of his own desire, resumed the acid drink, and on one occasion took as much as 125 grains of acid in the course of twenty-four hours. During the last fortnight of his stay in hospital, he had no severe pains in his joints, and whenever flying pains warned him, he discontinued the medicine for a day.

While the above case was under my care in the hospital, it so happened that another diabetic patient of mine, in visiting the wards, met Wright and compared notes with him. From him he heard such a favourable report of the acid treatment, that he requested me to order him the same medicine if I thought it suitable. I did so. A drink consisting of seventy-five minims of lactic acid in a pint of water was prescribed. Of this he took daily as much as contained thirty to fifty minims of acid; and on the fourth day he came to me complaining of a sharp pain in his right knee, which rendered the joint stiff, and made walking very painful. He also mentioned that he had less severe pains in his other joints, and expressed his opinion that he had caught a cold, which had produced rheumatism, a disease from which he had never before suffered. There was no swelling or redness of the knee or other joints. His skin, which had hitherto been harsh and dry, was soft and moist. The acid mixture was discontinued, and in two days the pains had entirely ceased. During the next month, he made several attempts to take the acid mixture, but it was always followed in a day or two by pains in the joints. Early in May, he managed to take the mixture for a week, and then was laid up with such severe joint-pains, that I was called to visit him, and found him in bed with

pains in his elbows, shoulders, ankles, and knees, and, as he said, all over him. None of the joints were swollen except the right knee, which was faintly red, decidedly swollen, and very tender and painful. The other joints were simply stiff and painful on movement. The skin was freely perspiring. Pulse 96, full and soft. The acid mixture was stopped, the joints were wrapped in cotton-wool, and alkalies administered. In the course of a week, all the symptoms had disappeared, and the patient was able to walk about and resume his ordinary habits. This patient had never passed more than twenty-four grains of sugar an ounce while under observation. The excretion was generally not over fifteen grains an ounce.

**REMARKS.**—The above record contains an account of the joint-symptoms which were observed in two cases to follow the administration of lactic acid. In the first case, at least six well marked arthritic attacks occurred; in the second case, under conditions less favourable for observation as to duration of treatment and place, one well marked attack occurred. The phenomena corresponded in all respects to those which are characteristic of acute articular rheumatism. They came on when the acid was taken, and ceased when it was discontinued. When moderate quantities of the acid were tolerated, an increase in the dose was succeeded by the painful inflammation of the joints. Coinciding with the development of the articular affection was the appearance of perspiration, at first only slight, but afterwards, in the more severe attacks, copious and acid.

These facts have dispelled the last lingering doubt in my mind as to the truth of the lactic acid theory of rheumatism. At first I doubted the connexion between the administration of the acid and the production of the rheumatic phenomena. In my scepticism, I regarded it as an accidental combination. The recurrence of the joint-symptoms, however, on March 13th, following distinctly on the repetition of the lactic acid mixture, shook my disbelief. The coincidence of joint-attacks with the use of the drug might occur once, and I thought even a second time; but, when I found it occur over and over again, there was no room left for the hypothesis of coincidence. To refer Wright's attacks to a series of accidental combinations requires, in my opinion, a much livelier faith than to accept the lactic acid theory of acute rheumatism. If to some, Wright's case presents not evidence enough in the beautifully typical character of the artificially produced disease, and in the precision with which it could be manufactured at the will of the experimenter, then the second case comes in to refute any explanation founded on the assumption of an idiosyncrasy on the part of one patient.

In health, no doubt, much larger quantities of lactic acid than any given in my cases would be excreted without producing any perceptible disturbance in the bodily functions. The acid would escape by the skin, the kidneys, or, after oxidation, as carbonic acid and water. It cannot be justly argued that the quantities of acid taken by my patients were too small not to have escaped in this way. The conditions under which the drug was given must be borne in mind. In diabetes we have a state of suboxidation very unfavourable to the conversion by oxidation of new compounds; and in Wright's case this was aggravated by the serious pulmonary complications. Associated with these, there was a dry and branny state of the skin highly unfavourable to the elimination of the lactic acid by one of the common channels. Lastly, the well known persistent acidity of the urine in diabetes points to a pre-existing hyperacidity of the fluids. These considerations are, I think, important, as defining the conditions under which the experiments were made—conditions most favourable to the development of the specific effects of the lactic acid. It was the combination of all these which rendered Wright so susceptible to the action of the drug. By the absence of one of them (the lung-complication), and the minor degree of glycosuria, we may probably explain the slighter susceptibility in the second case. The larger doses of acid which Wright was able to take occasionally, towards the close of his stay in the hospital, find an explanation partly in his more careful management of the remedy, partly in an acquired toleration of it, and partly in the great improvement which occurred under treatment in the state of the respiratory organs and in the sugar-excretion.

I refrain for the present from discussing the bearings of my observations on the therapeutics of rheumatism. The effects of the lactic acid on the excretion of sugar will be considered, with other modes of treatment, in a future paper. In this communication, my object has been to lay before the profession facts which have an important bearing on the origin of a common and serious malady. If, by pointing out the nature of the poison of acute rheumatism, they help in the smallest degree to improve therapeutics, they will not have been observed in vain.

## ABSTRACT OF A CLINICAL LECTURE ON A CASE OF RUPTURED OR LACERATED KIDNEY, FROM A RAILWAY ACCIDENT: SUPPOSED FRACTURE OF THE OS PUBIS, AND RECOVERY.

*Delivered at St. George's Hospital on October 24th, 1871.*

By PRESCOTT HEWETT, F.R.C.S.

Surgeon to St. George's Hospital; Surgeon-Extraordinary to His Royal Highness the Prince of Wales; &c.

THE case to which I intend to call your attention to-day, gentlemen, will be of interest, as the injury is not a common one, and not unfrequently terminates fatally. The man is lying in the Oxford Ward; and, from the symptoms which he had, I suppose he has had rupture or laceration of the kidney. He is a fireman on the railway, and while on the line he was caught between two carriages, the buffers compressing the lower part of the belly and pelvis. I mention especially the lower part of the belly and pelvis, because we shall have to determine whether there has been injury of the pelvis. When brought in, he was in a state of collapse, complaining of great pain in the lower part of the belly, and especially in the left loin. Now, in an accident of this kind, it is not easy at first to tell which organ is injured. After awhile, however, if the man pass urine, and you find that there is blood in it, you may fairly suppose that his kidney is lacerated. Well, after this man had been in the hospital some time, he passed blood in his urine; and, as the pain was in the left loin, it was inferred that it was the left kidney which was ruptured. For a day or two he had still more pain, and then there came symptoms of peritonitis, spreading from the left side down into the iliac region. He was admitted on the 27th September, during my absence. On October 2nd I saw him. During these few days he was under the care of Mr. Rouse, and was treated for laceration of the kidney and peritonitis. He was somewhat recovered when I saw him; blood was no longer passed in the urine, and the peritonitis, ending in marked thickening, was subsiding, insomuch that he was lying perfectly flat on the bed, and his legs were stretched out. You will bear in mind that the mere posture of the patient is an indication of his state, especially when the injury is about the belly, and has led to peritonitis.

Now what had been the treatment in all this mischief? It was that of perfect rest and opium. It was under this treatment that he so much improved. The only thing which I had to do was to carry it on. He went on gradually improving, and within a fortnight the whole of the hardness about the left side of the belly had disappeared; there was not the slightest pain, and the pulse was natural. The opium was gradually left off, and the man was put upon a better diet. He is going out to-morrow, about a month after the accident.

The mischief in this case was evidently in the front part of the kidney. I believe this from the fact of the patient having peritonitis. You will find that I have reason for believing this from the anatomical relation of the kidney—covered in front by the peritoneum, but behind by cellulose-adipose tissue. Had the rupture been behind, diffuse cellular inflammation would have occurred, and not peritonitis.

And now as to the probable injury of the pelvis. About a week ago, the man was allowed to get up and walk about the ward. He did this for a day or two, and then began to complain of pain in the right groin. I made him lie down in bed, and examined him, and I there found an extravasation of blood, which had not existed there before. It was exactly as if he had been bruised. This ecchymosis of the skin did not make its appearance until three weeks after the man had been in the hospital. What did this discoloration of the skin here mean? In the injury he met with, there must have been some extravasation of blood on the right side in the iliac fossa; and I strongly suspect, from the limitation of the ecchymosis, that this man has had a fracture—probably a mere crack—of the horizontal branch of the os pubis. These discolorations of skin, appearing some time after severe injuries, are most useful in the diagnosis of fractures which have not been suspected. I am all the more induced to call your attention particularly to this point, because I find no mention made of the fact that discoloration, thus appearing over the sternum may lead to the diagnosis of a fracture of this bone, when there was no direct injury done to this region, but to the spine.

Now with such an accident as extensive laceration of the kidney, is it possible for the patient to recover? I have seen many cases in our wards in which I have had no doubt that there was extensive laceration, and in which recovery took place. This is one of these cases. The man has had laceration of the kidney, if the symptoms indicate anything. He may by and bye have, it is true, some ulterior mischief in this region, but he has recovered meanwhile. I have placed upon the table

a specimen of the same kind, which is very interesting. The patient was in this hospital, and you will find all the particulars in the Museum Catalogue, Series xi, No. 4. This man had, it was evident, extensive laceration of the kidney, from which he quite recovered; but two or three months afterwards he died of typhoid fever, and the healed laceration of the kidney was found. There can be no doubt about this case.

I have given you already the plan of treatment which you should adopt when peritonitis ensues in these cases. But when the laceration is at the back of the kidney, and diffuse cellular inflammation occurs in the loin, you must make a free incision to prevent burrowing.

The treatment of lacerated kidney is, for the most part, as I have told you, very simple; but much to my surprise, a new plan of treatment was given to me some years ago when I was examiner at the Army Board. It was to "cut out the injured organ—an operation which has not unfrequently been performed with success"! This answer was given to me in writing by a gentleman who possessed two diplomas! I need not tell you that this treatment I would not advise you to follow.

This patient, as I have said, is going out to-morrow; but he has been warned to be very careful in everything, but especially as to walking and going about much, owing to the injury which I suspect he met with about the pelvis.

## ABSTRACT OF A CLINICAL LECTURE ON DROPSY.

*Delivered at St. Thomas's Hospital on November 2nd, 1871.*

By CHARLES MURCHISON, M.D., F.R.S.,

Physician to St. Thomas's Hospital, and Joint Lecturer on Medicine at St. Thomas's Hospital Medical School; etc.

AFTER noticing the general nature of dropsy, and tracing it to the osmotic circulation constantly going on in the tissues of the body, and between the vascular system and the serous and mucous membranes, Dr. Murchison said that the causes of dropsy may be reduced to two heads—(1) excessive venous repletion, and (2) diminished exhalation in one part of the body, leading to compensatory exhalation in another. There are some other causes, he said, which you will find mentioned, and which may contribute to the existence of dropsy: one of these is an altered condition of the blood. No doubt this may assist in the production of dropsy, as in *anæmia* or *hydræmia*, when the blood passes more easily through the membranes than in the state of health; still, in the dropsy of *anæmia*, you will find the heart at fault mainly: there is a deficiency in its propelling power. There is a general impression that, in renal disease, the dropsy is due to an altered state of the blood; but I shall give you some reasons for a different conclusion—that the dropsy from kidney-disease is to be explained by the second general cause which I have mentioned. Some writers speak of dropsy as sometimes having a nervous origin; and cases of dropsy, associated with paraplegia, and even with hemiplegia, have been recorded by Dr. Laycock of Edinburgh, in support of this view. But this cause of dropsy is certainly far from common. It is very important to remember the two main causes of dropsy, for the key to the whole treatment depends upon them.

Dr. Murchison then divided the forms of dropsy, from a clinical point of view, into three: 1. Partial dropsy, or dropsy limited to one part of the body throughout its course; 2. Dropsy which is first partial, but becomes general; and 3. Dropsy which is general from the first. The first form is due always to excessive venous repletion; and this overdistension of the small veins is the result of some mechanical impediment to the venous circulation. Dr. Murchison illustrated this by various examples, and called particular attention to the clinical characters of the dropsy due to obstructed portal circulation; viz., the beginning of the dropsy in the abdomen; the dyspnoea following, but not preceding, the ascites; the tendency to hæmorrhoids, vomiting, and diarrhoea, or to hæmatemesis; enlarged spleen and varicose veins on the right side of the abdomen. In the second form of dropsy, the swelling begins in the feet and proceeds upwards; and this also is due to excessive venous repletion, from obstructed venous circulation. But here the obstruction is in the central organ of circulation—most frequently mitral disease, or fatty heart, or dilated right side of heart, consequent on chronic bronchitis and emphysema. In the third form of dropsy, the swelling invades all parts of the body at once; and this is due to diminished exhalation in one part, leading to compensatory exhalation in another. This dropsy is almost invariably renal. Albumen is present in the urine. How is it that disease of the kidneys produces dropsy? On this point you will find great difference of opinion among different writers. In some works this question is rather evaded than answered; but the general view is, that in consequence of disease of the kidney, the blood becomes poisoned, and, as the result of this altered condi-

tion, the liquor sanguinis exudes. For example, Dr. Owen Rees, in the Harveian Oration a few years ago, made the remark that the retention in the blood of the urinary salts made the liquor sanguinis permeate the membranes with increased facility. But there is one very important objection to this view of the case—that, if it be correct, it is most remarkable that in the form of kidney-disease, in which of all others there is the greatest tendency to the retention of the urinary salts in the blood, there is little or no tendency to dropsy. I mean the contracted granular or gouty kidney, the peculiarity of which disease is, that the patients often die of uræmic coma and convulsions, with little or no dropsy. We must look, then, for some other cause of the dropsy. It is this: you get a diminished exhalation of water from the kidney; and hence dropsy is chiefly met with in those forms of kidney-disease in which the tubes are blocked up by diseased epithelium or inflammatory products (acute nephritis and fatty kidney).

Dr. Murchison then made some remarks on treatment. In the first place, one great object is to relieve venous repletion, which, in the case of portal dropsy, may be accomplished by purgatives, which cause a watery exhalation from the bowels. Another object is to remove obstructions to exhalation from the skin or kidneys by diaphoretics, warm baths, diluents, and diuretics. Thirdly, you must endeavour to stimulate compensatory exhalation from the skin and bowels. You will also find much good derived from tonics, such as iron.

Several cases in the hospital were commented upon as illustrating the above remarks, and the details were given of two cases now in the wards; viz., a case of ascites due to disease of the vessel, and a very remarkable case of general dropsy, in which there was no evidence of disease either of the kidneys or of the heart.

## VISIBLE PULSATION OF THE ARTERIA CENTRALIS RETINÆ IN A CASE OF INCOMPETENCY OF THE AORTIC VALVES.

By C. E. FITZGERALD, M.B., M.Ch.(Dubl.),

Assistant-Surgeon to the National Eye and Ear Infirmary, Dublin.

AT the Heidelberg Ophthalmological Congress held in September last, Professor Becker of Heidelberg, as my colleague Mr. Swanzy informs me, read a paper on Visible Pulsation of the Arteria Centralis Retinæ in cases of Incompetency of the Aortic Valves, and also showed a patient who exhibited the phenomenon. Quite recently I have had an opportunity of examining a well-marked case, which appears to me possessed of sufficient interest to make it worth while recording.

The patient is a man aged 40, who was admitted into the Infirmary of the South Dublin Union on the 3rd instant, under the care of Dr. W. B. Jennings, to whose kindness I am indebted in granting me permission to publish the following particulars. I do not think it necessary to give the history of the case; suffice it to say, that all the symptoms of incompetency of the aortic valves were present, and very well marked.

On the first occasion on which I examined the patient's eyes, I was able to detect in the right eye (the pupil being partially dilated with atropine) a very distinct pulsation of one of the retinal vessels, immediately at its point of emergence from the optic disc; this portion of the vessel presented such a dark purple colour, that, combined with its close proximity to one of the veins, which were somewhat congested, I failed to satisfy myself completely as to whether the pulsation was in the artery or in the vein. On a subsequent occasion, I again examined the patient several times, but was still unable to settle this point; a few days later, however, I dilated the pupils fully with atropine, and used a four-inch, in place of the ordinary two-and-a-quarter-inch convex lens. The large image thus obtained enabled me to determine clearly that the pulsation was certainly in the artery. Moreover, by resting the little finger of my left hand on the temporal artery, I found that its pulsations and those of the retinal vessel were synchronous.

It was in a portion of the superior branch (inverted image) of the arteria centralis, extending from its point of emergence to where it crossed over one of the veins, that the pulsation was visible; and I am inclined to think the difficulty of determining as to whether it was in the artery or vein was caused by the column of blood at each pulsation projecting this portion of the artery forwards; the rays of light were consequently no longer reflected directly from the walls of the vessel, which, in fact, became foreshortened and partially thrown into shade. I was unable to detect any pulsation in the retinal vessels of the left eye.

I may mention that there was no increase of tension in either eye; in fact, the tension of the right eye was, if anything, below the normal.

Dr. Becker states that the phenomenon is not invariably present in cases of incompetency of the aortic valves, nor is it at all times visible in those cases in which it has been observed. It was previously noticed by Dr. Quincke, assistant to Dr. Frerichs.

I am indebted to Dr. Purser for the sphygmographic tracings of the man's pulse.

### MANAGEMENT OF THICKENED OR DISEASED OMENTUM IN HERNIA.

By THOMAS LEEDS, Esq.,

Lecturer on Physiology in the Sheffield School of Medicine.

IN cases of hernia, where the sac has been opened and found to contain thickened or diseased omentum, what is to be done with the omentum? As the opinions of surgeons are still divided upon this point, I may, perhaps, be excused for describing the particulars of a case which has lately occurred in my practice. The plan of removing the omentum, applying ligatures, and returning into the abdomen, is, I believe, deservedly falling into disrepute. The best practice lies, it would seem, between the plans (1) of leaving the omentum in the wound; (2) of removing it and allowing the upper portion to remain in the wound; (3) of leaving the omental tumour outside the wound, and applying a ligature around it, with a view of causing it to separate, and of setting up adhesions around its neck. Various eminent surgeons, including Syme (*Principles of Surgery*, 1863) and Callender, recommend the first-named mode of practice. Mr. Callender says: "Unless, however, it" (*i.e.*, the omentum) "is unmistakably gangrenous, it should, as a rule, be left in the wound, and the wound should be left partly open for drainage. I never saw any result from removing omentum, except now and then a troublesome bleeding. I never saw any harm from leaving it in the wound; but I have seen the disastrous consequences of returning, even what one hears called 'not bad-looking' omentum, into the cavity of the abdomen." (*St. Bartholomew's Hospital Reports*, vol. iv). Mr. Callender elsewhere also urges the necessity of leaving a portion of the wound open for drainage. Of the second, or immediate removal plan, I know little; but, as there is some danger of hæmorrhage and its consequent debilitating effect upon the patient, and the possible risk of peritonitis through blood escaping into the abdomen, it seems to me inferior to the third plan—that of applying a ligature. In Holmes's *System of Surgery*, vol. iv, is given the result of some cases in which the ligature was successfully applied at St. George's Hospital (by Mr. Pollock, I believe). "Of twenty cases, in which the omentum was securely tied, a few died; but the notes of the after-death examination of these show the cause of death to have been, in all cases, independent of the ligature placed around the omentum. Of eleven cases in which the omentum was allowed to remain in the sac, many recovered, although abscess and sloughing of the tissue occurred in some of them."

CASE. — On November 3rd, I was sent for to see a woman, aged 61, who had been vomiting for four days, and was now throwing up sterco-raceous matter. The history of the case pointed to an irreducible hernia of six years' standing. The taxis having been tried, without success, assisted by my friend, Mr. Fayer, I cut down and found a pad of omentum, of the size of a large hen's egg, under which lay a knuckle of liver-coloured intestine. The stricture (at the external ring) was divided, and the bowel returned. Taking into consideration the length of time that the omentum had occupied its present position, it was deemed unsafe to return it. The omentum was left outside the wound; sutures being placed on each side, so as to constrict it, as far as possible, and to prevent the escape of fluids into the abdominal cavity. A ligature was afterwards placed tightly around the omentum. On the

tenth day, the removal was completed by means of the *écraseur*. There was scarcely any hæmorrhage. The patient recovered without a bad symptom throughout, and is now (November 18th) able to sit up. By thus constricting the neck of the tumour, this patient—an old woman—was saved from the chance of exhausting suppuration, which occasionally follows the plan of leaving the omentum in the wound, and from the injurious effects of troublesome hæmorrhage, which has been known to occur through the immediate removal of omentum.

In another case of a similar nature I should be inclined to use the *écraseur* earlier—about the fifth or sixth day—as adhesions would by that time in all probability have taken place.

### A PLAN FOR FACILITATING THE REDUCTION OF STRANGULATED HERNIA BY TAXIS.

By PHILIP CRAMPTON SMYLY, M.D., F.R.C.S.I., Surgeon to the Meath Hospital.

"THE objects to be attained in the treatment of hernia in a state of strangulation, are the release of the protruded parts from stricture, and their replacement within the abdomen, provided they are in a suitable condition." These objects are usually sought to be accomplished either by taxis or by operation with the knife."

Some years ago, a nurse in one of the medical wards in the Meath Hospital had a reducible femoral hernia. She neglected to wear a truss, and one day it consequently became strangulated. My father, being the surgeon on duty, tried taxis, as did also the other surgeons, without success. After consultation, an operation was decided on, but every argument failed to persuade the patient to submit—she would rather die than be cut. After the surgeons had left, the clinical clerk (since a very distinguished medical officer in the army) and I thought it a good opportunity to study the relation of the ring to the sac. The result of our examination not a little surprised us. On withdrawing my finger from the ring into which I had inserted it, we heard a distinct gurgle. My fellow-student pressed the tumour, and it passed into the abdomen. The patient lived for many years afterwards, and performed her duties in the hospital. I have since frequently tried to repeat this happy manoeuvre, and with most satisfactory results.

For inguinal hernia in the male, the index finger is applied to the lowest part of the scrotum. This is invaginated (as in Wutzer's operation for radical cure), the finger being passed behind the testicle and cord up to the external ring. The hernial tumour is then pressed down-

FIG. 1.—Scrotum invaginated.

wards over the finger towards the back of the hand, so as to make the structures in the ring tense, and consequently smaller. The invaginating finger is then forced firmly upwards and outwards in the direction of the internal ring. As soon as the finger is firmly grasped, the

hand should be slightly turned, and the finger pushed towards the middle line. Considerable force may be safely applied in this way, as

FIG. 2. - Finger pressing inwards.

all the delicate structures are behind the finger, which acts mainly on the stricture. On withdrawing the finger, the hernia can usually be easily returned. The same principle is equally applicable to femoral hernia. This plan may have occurred to others; but if so, it is perhaps not generally known, and any suggestion by which a cutting operation may be safely avoided is acceptable to the practical surgeon. My colleague, Mr. Porter (surgeon to the Queen in Ireland), was much pleased with the success of this plan in a case of inguinal hernia strangulated four days; and he has since tried it himself with satisfactory results.

The advantages which I claim for this procedure are—1. The strangulating portion of the ring is dilated before any pressure is applied to the bowel; 2. Much greater force may be applied to dilate than could safely be brought to bear when the intestine itself is employed for dilatation, as in ordinary taxis; 3. There is much greater probability of returning the bowel into the abdomen in a good condition, and, consequently, in a number of cases avoiding a dangerous surgical operation.

## CLINICAL MEMORANDA.

### THE IODIDES OF AMMONIUM AND SODIUM IN SYPHILIS.

It not unfrequently happens in cases where iodine is required, and the patient has taken iodide of potassium with good effect for a certain time, that this medicine either ceases to produce any result, or is no longer tolerated. *Faute de mieux*, mercury is sometimes resorted to; but, as the cases are not suitable for mercury, they generally become worse while taking it. In this difficulty, the iodides of sodium and ammonium are very useful, for they affect the body somewhat differently from the potassic salt. They can be borne by, and produce the effect of iodine in many persons who have become nauseated by the latter. They moreover contain less alkali per weight of the salt, and their alkali is less deteriorating to the blood than potash. One or two cases will illustrate my meaning. A gentleman was brought to me by his medical adviser, with extensive and obstinate syphilitic ulcers of the tongue and palate. He had had several other forms of syphilis during the nine or ten years he had been infected, and was in a weak and low-spirited condition. Early in the disease, he had taken mercury and other remedies in the usual way. Latterly, for the ulcers in his mouth, iodide of potassium had been given in doses gradually increasing to a scruple, and even half a drachm; but, when I was consulted, these had ceased to check the disease, and had produced iodism. In consequence of this, mercury and several other drugs had been tried again without benefit. Though his tongue was foul, his appetite, but for the pain of eating, was good. This is important; if the digestion be deranged, it must be set right again before iodine can have fair play. Under these circumstances, the patient was ordered to begin with eight-grain doses of iodide of ammonium in bitter infusion three times daily. He bore this well, and in the course of a few weeks his tongue and palate were nearly healed. For complete cicatrisation it was necessary to alter the form to

iodide of sodium; and, during two years, he has been taking this salt at short intervals to prevent the relapse of his disease. Here is another case of syphilis appearing unconquerable by either mercury or iodine, which had been given by several medical men whom the patient had consulted. The case was interesting from the probability of its being one of contagion through an infected monthly nurse "sucking the breasts." The child was infected at the mouth subsequently to its mother, and the history in the mother points to contagion having entered by the nipple. I did not see the patient until two years after infection; she had then severe ulceration of the tongue and of the soft and hard palate, and limited necrosis of the bone in the palate. From the prescriptions which she showed me, she had been taking scruple doses of iodide of potassium, for some time with good effect; but, latterly, even double doses of her medicine had only produced severe iodism without controlling the disease. It was with some reluctance that she consented to try iodine again; but, after a few eight-grain doses of iodide of sodium, coupled with frequent washing of the mouth with hyposulphite of soda and glycerine lotion, her sufferings were so far removed that she announced, a week afterwards, that she could eat crusts with ease; and, in a month, except that a morsel of necrosed bone still adhered, the mouth was quite well. The course of this case since has been obstinate; gummata appearing elsewhere after that in the mouth had healed; but she still takes iodine, sometimes in one salt, sometimes in another, and occasionally mixed with Bell's liquid extract of sarsaparilla. It would be easy to multiply instances where, iodide of potassium having lost its effect, the progress towards recovery can still be maintained by another form of iodine; but that is needless.

BERKELEY HILL, Surgeon to University College Hospital.

### EFFECT OF ROCKING ON TEMPERATURE.

THE *Journal of Anatomy and Physiology* for November, in its report on the progress of physiology, mentions some experiments of Manassein concerning the effect of "rocking" upon the temperature of animals. This gentleman found that by this means the temperature was lowered from 0.66 — 1.2 deg. C. It is not stated what animals were experimented upon; but, on repeating his experiments with infants, I have not met with a similar result. On December 19th, I took the temperature of four children, varying from six months to a year old, and found it to register as follows: 98—97.8 deg., 97.4—97.3 deg. F. They were then cradled and rocked for a quarter of an hour, and the temperature taken again, when precisely the same results were obtained as before the rocking.

S. MESSENGER BRADLEY, Manchester.

## THERAPEUTIC MEMORANDA.

### VACCINATION-PAPERS.

SMALL-POX having entered our hitherto healthy town, there has been a great demand for vaccination; and I have, at times, found difficulty in keeping up a regular supply of lymph. To meet this, I have devised a new method of lymph preservation; it is most portable, and very certain in its effects. Taking a sheet of common sized (*i. e.*, cream-laid) note-paper, I paint it with fresh lymph taken from the vesicle with a fine camel-hair pencil. The lymph soon dries; and the paper is ready for use. When required, a minute piece may be cut out or torn off the sheet, and, after having been slightly breathed upon, should be stuck upon the freshened surface. If the paper be required to be kept for any length of time, it should, after being charged, be covered with a thin coating of white of egg. Isinglass will not do, as it cracks when dried.

THEODORE J. PRESTON, M.R.C.S., Mansfield, Notts.

### CATHETERISM OF THE EUSTACHIAN CANAL.

IN Dr. Hibbert Taylor's paper on this topic, in the *BRITISH MEDICAL JOURNAL* of November 11th, he says that the introduction of the catheter is by no means difficult, requiring the possession of a certain amount of dexterity; but he does not describe the procedure. It may be useful to learn that Mr. Henry Power has, in his translation of *Kramer's Aural Surgery* (New Sydenham Society's edition), at pp. 28-29, very clearly rendered the steps to be taken. Other portions of Dr. Taylor's paper induce me to add some remarks. Kramer is strongly opposed to any other insufflation into the Eustachian tube than from the mouth of the operator, objecting to the use of "any caoutchouc bag, bellows, or air-press, either large or small" (p. 30, *et seq.*) At page 31, he mentions how the "position, extent, and tightness," of any contraction of the canal can be ascertained by the "introduction of a catgut or

elastic bougie"; and proceeds with the mode of applying those instruments. The blowing into the tube of nitrate of silver in solution (one to three grains of an ounce of water), or sulphate of zinc (five grains to an ounce of water), or hydrochlorate of ammonia, is recorded in pp. 102, 110, and 112; and dilatation by bougies at pp. 103, 107, and 112.

Dr. Taylor has done good service by inviting attention to this subject, and has mentioned some of the authors who have written concerning aural catheterism. Those who wish to study it will find some additional references in the appendix (p. 145) to Kramer's work.

Malvern Link, Nov. 15, 1871. STANLEY HAYNES, M.D.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### REPORT ON THE TREATMENT OF SCROFULOUS ABSCESS OF THE CERVICAL GLANDS.

It is remarkable that, in the treatment of so common an affection as scrofulous inflammation and abscess of the glands of the neck, there should be so much variance of opinion amongst surgeons. The notes on this interesting and familiar subject which we have collected, and of which we commence the publication this week, are, it will be observed, sometimes of a contradictory character as to the influence of remedies which have long been in repute in preventing the formation of pus, and as to the best method of evacuating the abscess when it has formed.

#### UNIVERSITY COLLEGE HOSPITAL.

So long as the enlarging lymphatic glands which ultimately form abscess are tender, and the skin is unchanged in colour, Mr. BERKELEY HILL applies an evaporating spirit lotion to the lumps themselves for half an hour twice or thrice daily. If the patient can keep up the evaporation longer than that, so much the better; but hospital out-patients can seldom afford time to do this, and a rag worn round the neck and occasionally wetted is usually more a warm than a cold application. When tenderness has ceased, or before it comes on, iodine ointment is rubbed into the skin over the enlarged glands, night and morning, till rubefaction is produced. Meantime, counterirritation is set up by painting an area of skin, not over but round the glands, on the nucha and shoulder; for example, with solution of iodine, one in five of water dissolved in half its weight of iodide of potassium being added. This usually vesicates in the course of a few hours, and the counterirritant action is kept up without repeating the vesication, by applying the liniment of iodine of the *British Pharmacopoeia* every day, or every other day, according to the effect produced. Sometimes Bullen's liquor vesicatorius of cantharides is used instead of the caustic iodine solution. This is painted in a narrow ring, half an inch wide, at two inches' distance round the enlarged glands, and solution of iodine, one part in twenty-four of water, is spread over the lumps themselves. It may be remarked, *en passant*, that in Mr. Hill's out-patient room for the last twelve months the methods of treating inflammation by counterirritants laid down by Mr. Furneaux Jordan have been tried extensively in strict accordance with that gentleman's direction. But the success consequent thereon has been so small, that counterirritants cannot be relied on to any great extent for controlling inflammation. In chronic inflammation of lymphatic glands, this mode of treatment appears more useful than in most other affections, and it is customarily employed even when the inflammation has advanced to chronic abscess. It seems clear that the adhesion and cicatrization of undermined patches of skin and closure of sinuses are more rapid when counterirritation is used. In acute abscess, hot fomentations, poultices, and early evacuation of pus are employed. Sinuses and deep irregular cavities are injected with the solution of iodine, one part in twenty-four of water, and compressed by a soft pad and strapping if that can be arranged. The enlarged and indolent glands that are sometimes exposed by the breaking away of the skin are either partially destroyed by a light application of potassa fusa, or stimulated to suppurate freely, as sprinkling them with red oxide of mercury and poultices. The general treatment consists in giving good food and clothing; in the removal of decayed teeth, should they be present; iron as potash-tartrate, perchloride solution, Farrish's syrup of iron, this latter form being very good for young children. When the patients are much debilitated, or their pasty aspect denotes amyloid degeneration of the tissues through continued suppuration, the Samaritan fund of the hospital is employed to

send the patients for a month to Eastbourne. Mr. Hill has employed sulphuret of calcium internally in several cases, but has never been able to perceive the slightest benefit to ensue from its administration.

#### ST. THOMAS'S HOSPITAL.

Mr. LE GROS CLARK never attempts to disperse (so to express it) glandular scrofulous abscess in the neck, simply because he thinks such attempts futile. He has tried setons and other expedients in opening such abscesses, but now uniformly employs a delicate and thin lancet or a cataract-knife for the purpose. Mr. Clark does not delay this operation till a large surface of skin is thinned, and always tries to anticipate the patchy reddening which often, in these abscesses, immediately precedes ulceration. If deferred too long, there is more risk of tear, by the drawing in, puckering, and adhesion of the skin, if it escape ulceration. The opening should be sufficiently free to secure unobstructed discharge of the contents of the abscess; the opening should not be unnecessarily meddled with; and the dressing should be as simple as possible.

Mr. SYDNEY JONES says that it is a matter of importance to diagnose true scrofulous glandular enlargement from glandular enlargement consequent on irritation of neighbouring cutaneous or mucous surfaces. We are too much in the habit of looking upon enlargement of cervical glands as necessarily scrofulous. In a large number of such instances amongst hospital out-patients, some source of irritation, such as scalp-eruption or sores, dirt, or vermin, might, with little difficulty, be discovered. In cases of glandular enlargement, when evidently not dependent on neighbouring irritation, iodine with potash or iron has been administered by Mr. Sydney Jones, combined or not with cod-liver oil. Locally, iodine paint has been applied in the early stages; and warm-water dressing on evidence of suppuration. Evacuation of pus should be carried out so soon as formed, if the pain be acute. When the case is more indolent, the opening should be deferred until the superjacent skin shows discoloration. A fine point of potassa fusa hastens the breaking down of the scrofulous material where such breaking down has not been complete in the formation of the abscess. Potassa fusa has been found by Mr. Jones of great service in destroying reddened and brindled or irregular cicatrices. The application is painful; but a beautiful white smooth cicatrix results.

Mr. MAC CORMAC thinks that the local treatment of scrofulous abscesses is of secondary importance to the constitutional. Pure air, improved food, and tonic medicines, should be ordered. External applications will never induce the absorption of these abscesses. As they frequently occur in the neck and under the chin, to avoid cicatricial deformity becomes of importance. This is of very common occurrence if the abscess be left to open of itself, since there is usually loss of skin and tedious healing. So soon as the presence of pus is determined, Mr. Mac Cormac would prefer to open the abscess-cavity by means of a small puncture with a tenotomy-knife, or else drain off the pus through the cannula of a fine trocar. The operation is thus reduced to the most trifling proportions. It may be frequently repeated, and it by no means interferes with any other form of treatment which may subsequently prove needful. If the surgeon have succeeded in improving the general health, the abscess-cavity may in this way be induced to contract, and finally to heal, and an unsightly scar wholly obviated.

Mr. FRANCIS MASON has a very decided plan of treating scrofulous glandular abscess of the neck. As soon as suppuration is fairly established, he makes a very small puncture with a tenotomy-knife at a depending part of the swelling, the contents being allowed to drain away spontaneously. Anything like pressure or rough handling, to favour evacuation, is especially avoided, as occasioning pain to the patient and increased irritation in the part. Water-dressing is applied, or the patient is directed to bathe the neck once or twice a day with tepid water. The wound thus made seldom completely heals, but generally scabs over. In a few days the scab is gently lifted off; or, if necessary, the puncture may be reopened with a probe, when none of the semi-purulent fluid peculiar to strumous abscesses again exudes. Now a pad of lint of suitable size is placed on the abscess, over which a strap is applied, so that, whilst the point of puncture is left uncovered, the walls are kept in close contact. The pressure thus maintained prevents the re-accumulation of matter, and appears to have the effect of modifying and ultimately arresting the secreting power of the lining surface. Mr. Mason disapproves of large incisions, believing them to be often the cause of the unsightly cicatrices observed in the neck of strumous subjects. Neither does he think well of the practice of allowing the abscesses to burst of their own accord; for the opening thus made by Nature often involves and destroys a considerable and irregular amount of skin-tissue, leaving a far larger and more unsightly scar than that—often scarcely appreciable—occasioned by the timely interference of the surgeon.

Mr. ARNOTT has employed various remedies for chronic inflammation of the lymphatic glands of the neck in scrofulous children, but without sufficiently encouraging results to wed him to any special treatment. Painting the skin over the glands with tincture of iodine has seemed to do no good. Somewhat better effects have followed the use of iodine ointment in the same way; but he has generally preferred incision of the skin in the neighbourhood, which he has practised with the view of causing the iodine to be taken up by the lymphatics, and carried by them directly to the diseased glands. He has tried in several cases the plan of extensive counterirritation of the back of the neck and below the gland-swellings, as recommended by Mr. Furneaux Jordan; but he has never yet seen any reason to prefer this remedy to any other. It has certainly not succeeded in his hands to anything like the extent which Mr. Jordan's recorded experience led him to expect. Where the glands have distinctly suppurated, he has long practised the method of passing a thick piece of silk cord through the swelling, and tying it loosely in, so as to permit of a continued drain of pus without any serious scar resulting; and in some instances the treatment has yielded excellent results. Pressure by means of carefully applied strapping has also seemed useful. In more advanced cases, free evacuation of the pus, and subsequent light water-dressings, have been used. But in all cases it has seemed essential to attend carefully to the diet—giving meat twice a day, with plenty of milk, and cod-liver oil where this may be readily borne; and to ensure abundant open-air exercise. Generally, iron has appeared to be clearly indicated, the form most beneficial being either the syrup of the iodide of iron or steel wine. In one case, very notable improvement seemed to follow doses of iodide of potassium and carbonate of potash, taken twice daily in warm milk, as recommended by Mr. Erichsen.

#### THE MIDDLESEX HOSPITAL.

Mr. HULKE treats indolent swellings of the lymphatic glands by painting them with a gentle stimulant, as tincture of iodine; but when there are pain, tenderness, and redness, he generally finds a tepid water compress of cotton-wool, covered with any impervious material, soothing and useful. When matter has formed, he prefers to make a small dependent incision, which leaves a much less disfiguring scar than if the abscess is allowed to break. Where an abscess has already broken, and there is an indolent ulcer enclosing portions of nearly insulated tuberculous gland-tissue, he destroys these with iodide of starch, and stimulates the ulcer with a weak watery solution of iodine. In exceptional cases it is, he thinks, well to clip away pieces of very thin undermined and floating skin. With these local measures he always combines tonics, and as much outdoor exercise as can be taken without fatigue.

Mr. HENRY MORRIS says that scrofulous abscesses of the glands of the neck present two varieties—firstly, those in which, though the glands are predisposed to disease owing to the scrofulous taint, the inflammation and suppuration run an ordinary and sometimes a rapid course, and terminate kindly; and, secondly, those in which the glands pass through their various stages slowly and tardily, continue to discharge for a long time after they have burst or been opened, or leave fistulous tracts, with perhaps portions of gland-tissue, exposed or protruding through the opening. The treatment must in all cases be general and constitutional as well as local. Fresh air and exercise, nourishing but varied diet, and a sleeping apartment which is well ventilated and not crowded, are as necessary as they are difficult in some cases to obtain. Moderately and wisely administered, stimulants are of benefit, especially where there is but slight disposition to take food. Amongst medicines, cod-liver oil is, Mr. Morris thinks, the most serviceable. Where anæmia is present, as generally is the case, the preparations of iron are important aids to treatment. The syrup of the iodide of iron, with some bitter infusion, such as quassia, or taken together with the cod-liver oil, is the one he prefers. In older patients, and if the general state of the patient do not contraindicate it, he gives the tincture of the perchloride of iron; in other cases the citrate of iron and ammonia; and in others ammonia and bark. In the local treatment of inflamed cervical glands, every effort should be made to prevent suppuration by warmth, fomentations, iodine applications, or blisters; and even after suppuration has occurred the abscess may, in some cases, be absorbed, while iodine tincture or ointment is being applied and the constitutional treatment followed up. In all cases, however, in which the abscess remains stationary, or the degeneration of the gland is increasing, or suppuration is extending into the surrounding tissues, a small but sufficiently free opening should be made, and the wound afterwards dressed with chloralum-wool or some other dressing into which pus can drain, and by which the abscess-cavity is protected from the air. If the skin be much thinned and the abscess of large size, and induration around it when the case is first seen, it may be advisable to

open it by destroying a portion of the skin with caustic potash: this sometimes stimulates the walls of the abscess to granulate healthily, and a less conspicuous cicatrix than otherwise is left. Fistulous tracts are best treated by means of solid nitrate of silver, or the solid sulphate of copper; and if a portion of the gland protrude, this may be treated in the same way by dusting over its surface the powdered sulphate. In some cases, where other means fail, and if there be not much disease of the tissues around, so that a good covering can be obtained for the parts below, the remnant of the gland may be extirpated with the knife; but this can but seldom be advisable or necessary. If healing be delayed by disturbance of the walls of the abscess being kept up by the muscular tissues in the neighbourhood, as by the platysma or sterno-mastoid, the best remedy is to restrain the action of the muscle by means of a light compress and some strips of plaster applied over the surface of the muscle.

Mr. ANDREW CLARK recommends scrofulous glandular abscesses to be opened as soon as fluctuation can be detected. They should never, he thinks, be allowed to burst. This may be done with the knife or with potassa cum calce, the latter not leaving such a scar. Should the abscess continue to discharge thin unhealthy pus, and burrow downwards into the tissues, this may often be arrested by dressing the sinus with lint smeared with paste of iodide of starch, which often produces a good effect when everything else fails.

#### ST. MARY'S HOSPITAL.

Mr. SPENCER SMITH thinks that, in the treatment of these glandular affections of the neck, we are not sufficiently impressed by the fact that scrofula is a constitutional disease manifesting itself in local affections; that these occur in the earlier stages of life, and are not often persistent; that they, comparatively with other lesions, affect the general system but slightly, and frequently change their seat of action, but must have opportunity for the exercise of their energies. With this view, he thinks that the glandular affections of the neck in scrofula are too frequently over-treated; that the local manifestation is too apt to be treated as a strictly local disease. It is better, he thinks, to let the constitutional disease disfigure the neck or destroy a joint than cause death by destruction of the lungs. As to local treatment of these glandular affections of the neck, he is of opinion that the use of iodine is much abused. It is commonly employed in such strength and so frequently as to become a powerful irritant; quite inconsistently, therefore, with the view above suggested. Leeches, again, mask the symptoms by counteracting for the moment an effort of Nature to produce suppuration. But there is a condition of the glandular swellings when, after protracted and abortive efforts of Nature to induce suppuration, a mass of glands is seen studded with small abscesses in various situations—i.e., in immature or incomplete suppuration; and in such instances, the free application of leeches will, by reducing the circulation in the already deteriorated tissues, speedily cause their final destruction by suppuration, and hasten cure, temporary or permanent. Scrofulous abscesses in the neck should be opened by the smallest incision consistent with due evacuation. In these sluggish suppurations we constantly observe unhealthy sores, margined by overlapping edges of congested, but yet lowly vitalised integuments, almost without an effort at the healing process; if such margins be destroyed by a rather free use of the potassa fusa, the removal of tissue will not only expedite the healing, but afford a healthy stimulus to the ulcer, and the resulting cicatrix will be much less deformed than if left to Nature.

When scrofulous glands in the neck commence to soften and threaten to suppurate, Mr. GASCOYEN endeavours to promote the formation of pus and disorganisation of the glands as speedily as possible. To this end, he paints the swelling, if indolent, with tincture of iodine, or covers it with the iodine or camphorated mercury ointment under a poultice, continuing the use of the latter constantly, and of the former applications according to the pain they occasion or the effect they produce upon the skin. If the swelling remain hard and the suppurative process go on very slowly, a blister will often hasten it; or, if there be pain, a leech or two will relieve this and expedite the formation of pus. In these cases, Mr. Gascoyen objects to an early opening of the abscess, unless it be deeply seated or there be some special reason for doing so—such as severe pain; injurious pressure upon surrounding parts; tendency for the matter to burrow, or to cause death of a large piece of integument, etc.; but he prefers to leave it until the glandular tissue is well broken down, and the pus is fast approaching the surface. For, if the swelling be opened before disintegration of the glands is advanced, an enlarged gland will often project between the edges of the wound, and form a fungous protrusion, which prevents the closure of the wound, until destroyed by escharotics or allowed slowly to break down of itself—a process which may require weeks or even months for its completion, and which will leave a chronic ulcer very difficult to heal.

Moreover, these scrofulous glands in the neck (as in the groin or elsewhere) will, under slight chronic inflammation, often become infiltrated with serum to such an extent as to fluctuate and cause reddening of the skin; and yet, after presenting the local indications of an abscess, the serum will sometimes become absorbed, and the swelling entirely subside. If, when in this condition, the glandular swelling be opened, only a few drops of serous fluid, with some blood, will escape, and the gland protruding will be long before it is destroyed sufficiently to allow the wound to heal. In these cases, care must be taken not to delay the opening of the abscess too long, so that sinuses be formed by the burrowing of the pus, or death of a large piece of skin result from its pressure. The treatment Mr. Gascoyen adopts is to make an incision into the abscess at the most dependent or the most prominent point; a small opening is, as a rule, better than a large one, as lessening the risk of the skin sloughing. If the patient be in the Hospital, he advises opening it under the carbolic oil, and treating it according to Lister's method; but if he be an out-patient, this treatment cannot be carried out properly, and Mr. Gascoyen then employs poultices until the discharge diminishes, when he changes them for the zinc or calamine ointment; and if there be an indisposition to heal, he combines these with stimulating lotions or nitrate of silver. Should the edges of the wound remain livid, undermined, with no tendency to adhere to the subjacent parts, they should be removed by the knife or scissors; and if a gland protrude it may be cut away, or, better still, on account of the bleeding which sometimes follows, it may be destroyed by the application of nitric acid, nitrate of silver, potassa fusa, the nitric oxide of mercury in powder, etc., under a poultice or an ointment. Internally, the usual tonics, especially iron and cod-liver oil, should be given, with plenty of nourishing food and a small quantity of stimulant.

Mr. A. T. NORTON's sole treatment is to open scrofulous glandular abscess of the neck before discoloration of the skin takes place, by means of a small incision, and then to inject them with a solution of carbolic acid, one part in twenty of water. By this means he is enabled usually to avoid poulticing. Where there are extensive nodulated cicatrices which have been in existence for a long period, he cuts the cicatrix away, and brings the margins finely and closely together. The mark left is scarcely visible; and in some people such an operation, where available, is of very great importance.

#### EDINBURGH ROYAL INFIRMARY.

Dr. PATRICK HERON WATSON thinks that scrofulous glandular abscess of the neck can generally be referred to some peripheral irritation recent or remote—e.g., eruptions on the scalp or behind the ears; suppurating conditions of the face; primary or secondary dentition; the decay of teeth, and the formation of gumboils; various forms of stomatitis; or affections of the throat and tonsils. Dr. Watson fancies that such conditions, continuing in action, should form an important element in the early treatment of the glandular swelling which precedes abscess. Mineral waters or medicinal preparations containing the chloride of calcium are beneficial: tincture of cantharides and the salts of iron have also appeared to him much more efficacious than any other means of general medication. Locally, in the early stage, warm fomentations, or the application of cotton-wool over the swollen and tender surface, will usually give most signal relief. Painting with iodine has always seemed to him hurtful. If the suppuration occurs with any degree of acuteness, simple evacuation will generally be found sufficient. When the suppuration is tardily attained, blistering with cantharides is an excellent means of hastening progress. After such chronic abscesses have been opened, pressure should be employed to squeeze out any curdy concretions. The introduction of a stick of chloride of zinc to act upon the suppurating surfaces, or the injection of a strong solution of the chloride of zinc (fifteen grains to the ounce of water) into the sac, will materially hasten the progress towards second cicatrization. After evacuation of the abscess in any case, the part should be dressed with any of the antiseptic materials fashionable at the moment.

In treating scrofulous glandular abscess of the neck, Mr. ANNAN-PRAE practices early incision and treating the wound carefully, according to Lister's method. When a single gland is diseased and is acting as a source of irritation, he excises it, if possible, before the surrounding textures and then have become much involved. Proper constitutional treatment must accompany any local interference.

Mr. JOSEPH BELL treats scrofulous abscesses of the neck in the following manner. Before they have softened, he blisters them at short intervals, giving the patient good food and milk liquor, with cod-liver oil, and, in some cases, small doses of the tincture of hygie, as recommended by the late Mr. Syms. Ten drops a day largely diluted will be a full dose. After the glands have begun to soften, he uses blisters or other counterirritants to aid in the breaking down of

the gland-structure, but opens the abscess with antiseptic precautions before the skin has had time to get thin or purple in colour. The opening is best done with the aid of chloroform, and should be very thorough, as much as possible of the curdy pus and gland-débris being squeezed out of the wound, and the parts well washed out with an antiseptic solution. If the skin is already thin and undermined, it may be necessary to destroy some of it with caustic potash to prevent an ugly scar. Mr. BELL has tried the method of frequent evacuation of the contents of the abscess by a fine trocar, but has not seen reason to be satisfied with the result.

#### ROYAL INFIRMARY, ABERDEEN.

##### CASE OF ACUTE DIABETES, WITH CLINICAL REMARKS.

By J. W. F. SMITH, M.D., Physician to the Infirmary, and Lecturer on Clinical Medicine.

DIABETES, in the vast majority of cases, is a chronic disease; occasionally, however, it assumes an acute form, of which the following case is an instance; and Dr. Noble has recorded two similar examples in the BRITISH MEDICAL JOURNAL for 1863, vol. i.

CASE.—John Grassick, a farm-servant, aged 16, was admitted into the Infirmary on the 25th January, 1871. According to the testimony of his father and himself, he had only been ill about four weeks, the prominent symptoms being loss of flesh, weakness, constipation, increased urinary secretion, and great thirst. Excessive desire for food had never been complained of. Next day, it was found that he had passed eleven pints of urine in the twenty-four hours, of a pale-greenish colour, with a specific gravity of 1036, and which, when tested, contained a large quantity of sugar. He had no cough. The lung-sounds were normal. On the 28th January, he had passed eight pints of urine since the previous day at noon; and the nurse reported that he was taking little or no nourishment, and that he was very weak. His pulse was 80, and feeble, and he seemed restless and uneasy. His tongue was dry, and his bowels had been opened by an enema. He was ordered beef-juice and six ounces of wine. His temperature at 9 P.M. was 97. On the 29th January he was much worse; his pulse being irregular and very weak, and his mind confused. The temperature at 11 A.M. was 92.5. Soon after this he became comatose, and he died at 9 P.M. Every effort was made to get a *post mortem* examination, but it was not allowed.

REMARKS.—This case of diabetes seems to have run its course in four weeks. I could scarcely credit the short duration of the illness; but the father was most positive in his statements as to the lad, having been in good health five weeks previously, and as to the sudden onset of the symptoms of thirst, weakness, and loss of flesh. In the absence of a necropsy, no decision can be arrived at as to the cause of the diabetes, but I am inclined to think that it was of cerebral origin. It is very probable, also, that as he came a distance of more than thirty miles to the hospital (and only a part of that by railway), during very cold and frosty weather, his vital powers had been depressed, and his death accelerated by the journey. Dr. Prout used to remark on the frail tenure of life held by diabetics, and how the fatigue and excitement of a long journey to consult him caused a rapidly fatal termination in several instances: at the same time, I believe that the fatal event would not have been long delayed even had Grassick remained at home.

In all the cases of diabetes in which I have taken a note of the temperature, it has been below the normal, and this is the general experience. In a case that I had lately, the temperature, when taken at night, was at first almost at the normal, but this was only for two days; after that it varied, never exceeding 97, and sometimes being as low as 94 and 95. In another case, where there was the complication of phthisis, the temperature, in place of being raised, as it almost invariably is in ordinary cases of tuberculosis, was lowered, and stood at 97.

Phthisis is one of the most frequent terminations of diabetes; but, in the experience of Dr. Pavy and Dr. Wilks, it consists of a chronic pneumonic inflammation, leading to excavation and the formation of cavities without the existence of any tubercular deposit. In my case, however, the right lung was loaded throughout with tubercle, softened in several places with cavities; the left lung, also, contained a few spots of tubercle, but not broken down.

The treatment of diabetes is mainly dietetic, but every now and again some new remedy is proposed for it. Opium is often of great service.

It soothes the irritability and distress of the patient, which are often very marked, and it diminishes considerably the quantity of urine, but at the same time the specific gravity is raised. I have never given more than six grains in the day, although there is a great tolerance of this drug in diabetes; and there are cases on record where as much as a drachm has been given in the twenty-four hours.

### LEEDS GENERAL INFIRMARY.

#### MYELOID DISEASE OF LOWER JAW: REMOVAL OF HALF THE BONE.

(Under the care of Mr. JESSOP.)

DANIEL FOLEY, aged 10, was admitted towards the end of October 1871. About Christmas, 1870, his left cheek was observed to be a little swollen, but it was not until August last that the lower jaw presented anything like a distinct tumour. Since that time the growth of the disease was rapid. Throughout there was neither pain nor deterioration of health. On admission, the left cheek presented a prominent swelling over the body of the lower jaw. Beneath the jaw were two movable and painless lymphatic glands, each of the size of a field-bean. On examining the interior of the mouth, a tumour was found on the outer aspect of the lower jaw, reaching from the left middle incisor tooth to the angle of the bone. The growth had a firm semi-elastic feel, and the mucous membrane covering it was superficially ulcerated. The teeth on that side were all pushed towards the interior of the mouth. It was decided to remove the bone at the joint, and to divide the jaw on the right of the symphysis. Accordingly, on November 2nd, the right middle incisor tooth having been extracted, an incision was commenced over the angle of the jaw, carried along the

the doubtful character of the tumour; of the many varieties of new growth found in connection with the alveolar processes. Myeloid was by far the most common, and there was nothing in the present case inconsistent with what had been previously observed in myeloid disease; and yet the rapidity of its growth, the early ulceration on its surface, the youthful age of the patient, the presence of enlarged glands which, however, were not fixed, pointed to the possibility of malignancy. It was because of this possibility that it had been deemed prudent to take away so large a portion of the bone. In removing the lower jaw at the joint, it had been usual to commence the incision over the joint, to carry it straight down to the angle, and thence along the margin of the jaw to the symphysis. The incision adopted in the present case, although it involved cutting through the lip, had the great merit that it avoided division of the facial branches of the portio dura, and of the salivary duct. The removal of the bone was, moreover, effected with considerable facility. On microscopic examination, the tumour proved to be a well marked example of myeloid.

## THERAPEUTIC RECORD.

**POPLITEAL ANEURISM CURED BY FLEXION IN THREE DAYS.**—The *Bulletin de l'Académie Royale de Médecine de Belgique* contains an account by Dr. Larondelle of the cure of a popliteal aneurism of the size of an orange. Dr. Larondelle adopted Mr. Ernest Hart's method of forced flexion of the leg upon the thigh. There was oedema of the foot and leg. The bandage employed was applied after the fashion recommended by Mr. Hart in his first paper in the *Medico-Chirurgical Transactions*; and the patient, as in his second published case, was allowed to walk about the room with the help of a crutch. The bandage was solidified by starch. The flexion seems to have been forced a little in excess. At the end of the second day, as the patient was complaining much of the pain, the bandage was removed. The pulsation was less. A second bandage was applied, and on the third day the tumour was found to be solidified. The cure thus effected was permanent; and the tumour, at the end of five months, was reduced to the dimensions of a small hard kernel.

**TRANSFUSION OF BLOOD.**—Three interesting cases of transfusion are recorded by Jürgensen (*Centralblatt*, No. 28). The first was a case of phosphorus-poisoning. The patient was reduced to the last extremity of weakness, and suffered from hæmorrhage and jaundice, when, two months after the poisoning, about 580 cubic centimeters of blood, taken from three healthy persons, were injected into the median vein. Nearly the same quantity of blood was at the same time taken from the radial artery. He began to recover immediately, and in a month could leave his bed. A syphilitic eruption, from which the patient was suffering at the time, disappeared after the transfusion, and did not return till two months afterwards. In the second case, the patient was a young woman in a state of extreme debility from gastric ulcer, to which had succeeded peritonitis and pleurisy. The blood used in the operation had to be brought some distance to the patient's residence in small well-closed bottles. It had been previously defibrinated, and before use was warmed to the temperature of the body. At the first operation, 350 cubic centimeters were injected into a deep vein of the arm; and, ten days later, a smaller quantity into the peripheral end of the radial artery; while the same quantity was allowed to flow from the central extremity. This had no favourable result; and death subsequently ensued, after the evacuation of the pleuritic fluid by paracentesis. The third case was that of a man poisoned by exposure to carbonic acid in the hold of a ship. Nearly a day after exposure to the gas, the patient was quite unconscious, and had irregular and interrupted respiration and paroxysmal muscular contractions, while the reflex irritability was quite lost. In this case, 400 cubic centimeters of blood were drawn from the median vein; and thereupon 375 cubic centimeters of defibrinated blood, taken immediately before from three other persons, were injected into the same vessel. During the operation, the muscular spasms ceased; and after the patient had been for one hour in a warm bath, and subsequently had cold water poured over him, he was able to open his eyes and to drink. Three hours later, he answered questions; and on the next morning consciousness was perfectly restored. Recovery was complicated by the formation of red macule, which subsequently became gangrenous, on the skin. These were seen at the time of the operation, and presumably were due to stoppage of minute vessels. Jürgensen regards transfusion of blood as a most valuable remedial measure in carbonic acid poisoning, and advises an early recourse to it.

Fig. 1 shows the portion of the jaw removed with the tumour.

margin to the symphysis, and then turned upward through the centre of the lip. The lip and cheek having been dissected off the tumour, the jaw was cut through where the tooth had been extracted. The bone was then turned up, and with a few touches of the knife was dissected out at the joint, this part of the operation being much facilitated by cutting through the coronoid process with bone-scissors. The flap

Fig. 2 is taken from a photograph of the boy on the day before his discharge from the hospital.

was then adjusted and retained by wire sutures. Healing by first intention took place, and the boy was sent home on December 29th.

Mr. Jessop remarked to the students assembled in the theatre upon

**VACCINATION WITH GLYCERISED LYMPH.**—Dr. Weiss has contributed some important statistics on this subject to the *Vierteljahrsschr. für gerichtl. und öffentl. Medizin*. His observations were made during an outbreak of small-pox among the war-prisoners at Alt-Damm in December 1870 and January and February 1871. He first vaccinated three children with lymph mixed with glycerine, brought from Berlin. The lymph taken from these children was mixed with glycerine; and, from January 16th to March 6th, he revaccinated with the diluted lymph 5,801 men, the operation being successful in 1,586 cases. All the subjects had been vaccinated in youth, many two or three times; and in 4,023 there were distinct cicatrices. From November 21st to January 21st, among 2,687 men, there were 72 cases of small-pox, with 7 deaths. After the revaccination, from January 25th to April 15th, among 8,851 men, there were 195 cases, with 22 deaths; viz., among the successfully revaccinated, 6 cases, no deaths; among those in whom revaccination did not succeed, 25 cases, no deaths; among the unvaccinated, 164 cases, with 22 deaths. Dr. Weiss mixes the lymph from the arm with five parts of glycerine and the same quantity of distilled water. He says that, placed in bottles covered with bladder, it remains good for a long time.

**POLYGONUM HYDROPIPER AS AN EMMENAGOGUE.**—Dr. J. S. Unziker speaks highly (*Philadelphia Medical and Surgical Reporter*, October 14) of the polygonum hydropiper or water-pepper as an emmenagogue. Its saturated tincture, in teaspoonful-doses three or four times a day, was recommended by Eberle in cases of amenorrhoea. Dr. Unziker says that it was formerly much used in Cincinnati, but has become disused in consequence of having fallen into empirical hands. He has found it efficient and useful. Where anæmia or other constitutional defects are present, these have first to be corrected. It is the safest and best remedy in cases where the general health is not impaired, but where the menses are checked by cold, mental emotion, or other like causes, where it is wished to bring them on without fear of producing congestion in the head or chest.

**TREATMENT OF BURNS.**—Dr. de Bruyne uses, in place of Carron oil, or Velpeau's modification of it by using oil of almonds, a compound of 3 parts of partly precipitated hydrate of lime, 150 parts of glycerine, and 3 parts of chlorinated hydrochloric ether. The lime and glycerine are slightly warmed, and the ether is added. The product is a transparent uniform fluid. A piece of fine linen, soaked in it, is laid on the burn; and over it is placed oiled silk or some other covering, so as to prevent the access of air and the evaporation of the ether. Dr. de Bruyne has found this dressing useful in burns unattended with sloughing, and also after the detachment of sloughs. He thinks that it may be useful in ill-conditioned wounds, and in atonic, callous, fungous, and foul ulcers.—*Montpellier Médical*; and *Bull. Génér. de Thérap.*, December 1871.

**TREATMENT OF HYDROCELE.**—M. Monod, in a communication to the Surgical Society of Paris, has recommended, in cases of hydrocele, the withdrawal of a small portion of the fluid, and the injection of a little alcohol. This is repeated several times, until the hydrocele disappears. He relates several cases treated successfully in that way. His explanation of the *modus operandi* of the alcohol is, that it enables the fluid to undergo absorption, over which, in hydrocele, secretion predominates.—*Journal de Méd. et de Chir. Prat.*, December 1871.

**TREATMENT OF NAVUS BY SUBCUTANEOUS RUPTURE OF THE VESSEL.**—Dr. Mezger of Amsterdam describes, in the *Archiv für Klin. Chirurgie*, Band xiii, the case of a child who had a nevus a centimeter broad in the left ala nasi. It had a dark blue colour, which was deepened on prolonged expiration, the swelling at the same time being slightly distended. When seen, the child was three months old. The tumour was said to have slowly but steadily increased since birth. Dr. Mezger pressed one finger on the veins leading from the tumour, so that its capillaries were distended with blood; he then rapidly squeezed the nevus, so as to rupture the vessels while full. This proceeding was repeated on several occasions, commencing at the edge, and proceeding towards the centre. It was followed by extravasation of blood and slight inflammation. The result, Dr. Mezger says, was perfectly successful.

**CALCULI UNDER THE PREPUCE.**—The *Canadian Medical Journal* for October reprints from the *Pacific Medical Journal* a case related by Dr. H. W. Nelson, in which a Chinaman, aged 35, had phimosis, the result of an injury received in childhood. The opening for the passage of the urine was very small; and, during micturition (which was accompanied with much pain), the prepuce became distended to the

size of a fist. Dr. Nelson operated for the cure of the phimosis; and, in doing so, found in the preputial sac thirty-eight small calculi. The patient recovered well after the operation, and had no signs of calculus in the bladder. Dr. Nelson believes that the calculi must have been deposited from the urine which could not escape.

**CANCER OF THE ETHMOID BONE: EXTIRPATION: RECOVERY.**—In a statistical account of the University Clinic at Berlin for 1869, in the *Archiv für Klinische Chirurgie*, Band xiii, Dr. Busch relates the case of a man aged 78, who had a large tumour of the size of a fist occupying the middle of the face. It had partly destroyed the nose. In extirpating it, it was found necessary to cut close to the under surface of the cribriform plate of the ethmoid bone, and to completely open up the nasal cavity as far as the posterior nares. The defect in the face was remedied by transplanting a flap from the forehead, which had the result not so much of forming a new nose as of closing the hole left by the operation. Healing went on steadily, and the patient left the hospital in a few weeks.

## REVIEWS AND NOTICES.

**A PRACTICAL TREATISE ON BRIGHT'S DISEASES OF THE KIDNEY.** By T. GRAINGER STEWART, M.D., F.R.S.E., etc., Physician to the Royal Infirmary, Edinburgh. Second Edition. Edinburgh: Bell and Bradfield. London: Longmans and Co. 1871.

DR. GRAINGER STEWART is well known in connexion with the pathology and treatment of Bright's disease, and we are pleased to see that his work on this subject has already reached a second edition. Considerable improvements have been effected, and numerous additions made in the way of illustrations, new cases, and the subject matter generally. Of the more important additions, we would call attention to the records of the subsequent history and pathological conditions of several cases which had been under personal observation for several years. Dr. Stewart finds in them a full confirmation of his views regarding the pathology of these cases, founded on the symptoms manifested during life. The author adheres to the classification of Virchow, whose views he has further elucidated and in some degree modified. We do not at present propose to enter into any discussion as to whether the facts bear out this classification in all its details. The subject is, however, ably handled by Dr. Stewart; and we would refer to the work itself for the data on which the views regarding the nature of the different forms and stages of the disease are based. A valuable chapter has been added on the differential diagnosis of the different forms of Bright's disease. Supplementary chapters, embodying the results of original investigations previously published elsewhere, treat of other pathological conditions of the kidney, such as simple fatty degeneration, and its relation to Bright's disease; acute atrophy of the kidney; and the nature of waxy degeneration, in which Dr. Dickinson's views are fully discussed. An elaborate chapter has likewise been added on the complications of the different forms of Bright's disease, of great practical value. The treatment of Bright's disease is fully discussed. Altogether, the work before us will stand favourable comparison with the numerous treatises which have been written on this subject, and will take a high rank in medical literature.

## NEW BOOKS AND NEW EDITIONS.

*Mode d'Invasion et de Propagation du Cholera, étudié à Smyrne.* Par le Dr. W. CHASSEAUD. Constantinople: De Castro. 1871.—Dr. Chasseaud has rendered a service which epidemiologists will readily appreciate in writing the local history of the epidemics of cholera at Smyrna. The relations of Smyrna with Alexandria, with Constantinople, and with European ports, makes its epidemic history scientifically and historically valuable. Dr. Chasseaud traces it in great detail and with clearness. He is an enthusiastic believer in the transmission of cholera-poison along the lines of human intercourse and by human intervention. He calls it frequently contagious, and even (unwisely) refuses to consider how or by what means it is conveyed, whether by secretions, dejecta, or effluvia. Of course, therefore, he is the warm partisan of quarantines, and thinks that by a strict quarantine the invasions of cholera may be checked. A strict quarantine, in this country at least, is, however, little less than a sheer impossibility. In passing, we note that Dr. Chasseaud has proved the inutilty of various reputed prophylactics, and that he is disposed to regard the period of incubation as extending over five days. Treatment, he finds, as most others have done, modifies the disease but little. He looks upon cholera as a slight form of cholera.

## BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 23RD, 1871.

## PROLEGOMENON.

THE few words proper to this occasion may be brought within a small compass. The volumes of the JOURNAL for the year now about to end have contained a mass of scientific and practical original matter such as it has never before been the good fortune of the editor of any medical journal to be able to offer to his readers within a similar period. It is unnecessary to speak of it in detail; for the many thousands who have become possessed of these volumes have, if we may judge by the numerous communications which we have received and by the spontaneous compliments from foreign sources, fully appreciated the value of the remarkable series of lectures and original contributions which the JOURNAL has contained. To those who do not possess them, we are equally unable to offer any observation of interest; for a large part of the issue ran speedily out of print, and we have been unable to meet the demand for back numbers. We cannot, however, abstain from expressing our thanks to the Rev. Professor Houghton, Mr. Lister, Dr. George Johnson, Sir Thomas Watson, Dr. Gee, Dr. Hughes Bennett, Dr. T. K. Chambers, Dr. C. J. B. Williams; Inspectors-General Smart and Murray; Deputy Inspector-General Gordon; Drs. Beatty, Banks, Macnamara, and Grimshaw, of Dublin; Dr. Barnes, Mr. John Wood, Dr. T. L. Brunton, Mr. Haviland, Mr. Erasmus Wilson, Dr. A. Fleming, Dr. Crichton Browne, Dr. E. C. Seaton, Dr. A. T. Waters, Dr. H. Simpson, Dr. Bradbury, Dr. J. G. Swayne, Dr. Clifford Allbutt, and many others, for the kindness with which they placed at our disposal, for publication, scientific material of the highest value.

The influence which the JOURNAL has exercised throughout the profession, and in impressing the views of the profession on statesmen, publicists, and general readers, has never reached a higher point than during the last year. Its statements of fact and opinion have been repeatedly and respectfully discussed by the most influential organs of public opinion in London, and throughout the kingdom.

We shall endeavour at least to maintain, and shall not spare any fitting effort to overpass, the success and usefulness which have attended the career of the JOURNAL during the last year. Many years have passed since a new series of Lectures on the Practice of Medicine from one accomplished hand have appeared in any medical journal. The course of lectures on the Modern Practice of Medicine, which we shall commence in the first number of the new year, from the pen of one of the ablest, most accomplished, and encyclopædic of teachers, will, we are persuaded, prove eminently instructive and highly acceptable to the widest circle of professional readers. Dr. Murchison never fails to carry through whatever he undertakes with success and completeness; and we shall expect to be able to carry on the publication of these lectures with regularity. The communications of Dr. Oscar Liebreich of Berlin, the discoverer of the anæsthetic properties of chloral, upon this and three other new narcotic agents not yet known in this country, will be read with the greatest interest. The rest of the programme for the year speaks for itself; it is rich in promise; and we have every reason to anticipate that the promises will be fulfilled.

In this hope, and with the desire to make the JOURNAL continue to uphold and aid the best interests of the Association and the profession, we are emboldened to ask all the members of the Association and of the profession to continue the kindly and earnest support which has already given to the JOURNAL the high and useful position which it now

occupies, and to assist in making it worthy of an Association whose numbers, usefulness, and influence have increased to an extent beyond parallel. We number now more thousands of professional readers than were ever before represented by any journal in any profession. There is reason to hope that their number may be increased, until it includes the whole body of the active and working members of the profession.

## THE ANNUAL MEETING IN 1872.

THE Annual Meeting of the British Medical Association in 1872 will be held in Birmingham, the metropolis, no less medical than commercial, of the Midlands. Our members in that district are already making preparations to render the event useful and interesting. The President-elect of the Association, Mr. Alfred Baker, Senior Surgeon to the General Hospital, is widely known, and no less widely respected, throughout the midland counties. The profession is rallying round him with offers of assistance and of work; and a liberal subscription-list towards the expenses of receiving and entertaining this great Association has been formed, and is still increasing.

The Committee of Council, at their last meeting, appointed Dr. Fleming, Senior Physician to the Queen's Hospital, and Mr. Oliver Pemberton, Surgeon to the General Hospital, to deliver the Addresses in Medicine and Surgery respectively. The reputation of these gentlemen, and the resources of the Birmingham hospitals, are a guarantee of what we may expect from them. The number of Sections for scientific and professional papers is not yet decided. At present, four are proposed—Medicine, Surgery, Midwifery, and Public Health; and we believe that the claims of our provincial members will be largely recognised in appointing the officers of those Sections. In order to enable the members to attend the meetings more regularly than has occasionally been the case, it is proposed by the Committee of Management to repeat the practice which has been followed on some previous occasions, of providing each day a luncheon in close proximity to the place of meeting. We think that this will be a great advantage and convenience to the members and visitors, and that it will add much to the successful working of the Sections.

The Committee of Management met on December 14th, when various subcommittees were appointed for superintending the numerous requirements for the interest, the comfort, and the amusement of the members visiting Birmingham. The important department of the Museum is entrusted to the management of Professor Bracey, M.B.; and it will, we doubt not, be an important feature of the meeting. Mr. Clayton is Chairman of the Executive Committee. Mr. Bartleet, Honorary Secretary to the Local Branch, Dr. B. W. Foster, Secretary to the Pathological Section, and Mr. West, are the Honorary Secretaries. Mr. Taylor and Mr. Bindley are the Treasurers. Under their superintendence, there can be no doubt that the annual dinner, and the *soirée* which is proposed to be given by the President, and indeed the meeting altogether, will be thoroughly well arranged.

Birmingham itself may present fewer historical or archæological associations, and a neighbourhood less picturesque and less grand, than other places at which the Association has met. Its interest is that of industrial vastness and social character. Probably at no one place could one so readily see and investigate the complex machinery, the delicate arts, and exquisite processes, which are employed in ministering to the wants and luxuries of the world.

The various public buildings will be thrown open. The Hospitals, the College, the Gaol, the Lunatic Asylum, the Sanatorium, King Edward's School, the Midland Institute with its museum and art-gallery, the Free Library, and the Shakespeare Memorial Library, the latter the only one of its kind in England, will claim attention. The various manufactories, including Elkington's electro-plate works, with their gorgeous show-rooms and art-treasures; the mediæval and domestic brass and bronze work; glass works of every variety; the wire and tube and boiler works; the small arms manufactory, where all the Enfield processes may be seen; the manufacture of pins, of pens, of

papier-maché, of jewellery; the Mint; and innumerable other manufactures of things of artistic or domestic utility, will provide interest and amusement to our members. Permission will, it is confidently hoped, be obtained to visit many interesting places in the neighbourhood; among them, iron and coal pits; salt mines at Droitwich; the porcelain works at Worcester, where also the beautiful and recently restored Cathedral will repay a visit; and the beautiful inland watering-place, Malvern; Dulleigh Castle; Lichfield Cathedral; the Leachey Hills; Sutton Park; and the beautiful ruins of Kenilworth Castle; and Warwick Castle, itself now, alas! partly a ruin; and, though last, not least, Stratford-on-Avon, with its beautiful parish church and walk by the banks of the river, and the birthplace and residence of Shakespeare. With all these attractions, and with the known professional and social cordiality of our midland brethren, we confidently anticipate that the Annual Meeting of 1872 will be an era in the history of our Association.

### THE CONVALESCENCE OF H.R.H. THE PRINCE OF WALES.

THE health of His Royal Highness the Prince of Wales has continued steadily to improve during the week; and we are profoundly pleased to be able to state that his progress towards convalescence has not been marked by any interruptions, or by any other causes of anxiety than those necessarily incidental to the recovery from a disease so exhausting as a severe attack of typhoid fever. At the moment at which we write, we have the happiness of being able to state, from information dating late on Thursday afternoon, that defervescence is complete; there is a gradual return of power, and there are no visceral troubles. The exacerbation of fever which gave rise to the serious symptoms appears to have been the result of the severe intercurrent bronchial affection—an affection which of itself, as we had recently occasion to notice, is capable of raising the bodily temperature to 105 deg. This difficulty and danger having been happily surmounted, and having left so little trace, there is—we speak it with thankfulness and assurance—the best prospect of a very sound and complete convalescence. We must not count the weeks required to establish it with too great impatience; but above all things, we may rejoice that the fever has not left behind it any organic lesions.

For the re-establishment of the Prince's health, a mild winter resort may be useful. Osborne itself offers many advantages for such purpose. But this is still a speculation, rather than a forecast.

The Prince being happily so well restored, Sir William Jenner was enabled on Wednesday to return to town. Dr. Gull will return, it is expected, in a few days. These two eminent physicians have been in constant consultation and joint charge of his Royal Highness now for upwards of a month. The more immediate and continuous charge of the patient and the management of the sick room devolved from the first upon Dr. Gull, who was first in attendance. A very high, but by no means too high, tribute has been paid to the devoted, skilful, and ceaseless care which Dr. Gull brought to his anxious and all-important task. Never, indeed, was a malady so serious, and in a personage on whom the hopes and fears of a nation were centred, combated by a more fortunate combination of qualifications, capacity, and experience, than Sir William Jenner and Dr. Gull brought to their important task. We have the means of knowing that they were throughout closely united in opinion, act, and word upon everything which concerned the principles and details of treatment; and in all that they proposed and wished they were diligently—indeed indefatigably—seconded day and night by Dr. Lowe. None who know the admirable and gracious sensibility of the Queen and the Princess of Wales and the members of the Royal family, will fail to understand how fully the devotion of the medical attendants has been appreciated by those who themselves displayed in the serious events of the illness a ceaseless anxiety to do quietly, unobtrusively, and usefully, all that the most tender affection and well

directed but intense earnestness of purpose could suggest for the well-being of the Prince. Happy, indeed, is the conclusion which, under Providence, has crowned these efforts.

### CAUSE OF DIABETES.

A MOST interesting and important addition to our knowledge of the cause of diabetes has been recently made by Professor Cyon, in a paper which he, along with M. Aladoff, has communicated to the Imperial Academy of Sciences at St. Petersburg, and which is published in the *Mélanges Biologiques*. Several years ago, Claude Bernard put forward the theory that in diabetes the functional activity of the liver is increased, and a larger amount of sugar formed in it in consequence of the vessels of the organ becoming dilated, and the circulation in them more active. The increased activity of the circulation he attributed to some change in the vaso-motor system of the hepatic vessels, which allowed their walls to relax in a similar way to those of the ear of the rabbit after the sympathetic has been divided in the neck. He ascertained that the formation of sugar could be greatly increased, and diabetes produced, by galvanising the pneumogastric nerves in the neck, or by irritating their roots by puncturing them at their origin in the fourth ventricle. At the same time that the production of the sugar was increased by the puncture, the vessels of the liver became much dilated. It might thus have been supposed that the nervous influence which originated in the medulla oblongata and caused diabetes, passed down to the liver through the vagi. This, however, was not the case; for when these nerves were cut and their ends galvanised, diabetes was only produced by irritation of the central end, but not by irritation of the peripheral extremity. Diabetes could also be induced by puncturing the fourth ventricle, just as readily after the vagi were cut as when they were intact. If the splanchnic nerves were cut before the fourth ventricle was punctured, no diabetes was produced; but if they were cut after the puncture had been made, their section did not remove the diabetes which was present.

From these and other experiments, Bernard concluded that the air inhaled during respiration irritated the ends of the vagus in the lung; that this irritation was conducted up to the medulla oblongata, and was thence reflected down the splanchnic nerves to the liver, and caused the formation of sugar. By what way the nervous influence passed from the medulla to the splanchnics, however, was not ascertained; and no very satisfactory explanation could be given of the fact that section of the splanchnics after puncture of the ventricle did not remove the diabetes. Some light was thrown upon this question by the observations of Eckhardt and Pavy, but it has been reserved for Cyon completely to solve it.

Pavy noticed that section of the superior cervical ganglion of the sympathetic might cause diabetes; and Eckhardt found that it followed section of the last cervical or any thoracic ganglion, just as certainly as puncture of the fourth ventricle. Section of the splanchnic nerves did not produce it.

Eckhardt tries to explain this difference between the effect of dividing the ganglia and the nerves by supposing that diabetes is due to irritation of the ganglia by the exposure of their cut surfaces to the air, and that, when the nerves are divided between the ganglia, paralysis and not irritation is produced. If this hypothesis were true, diabetes should not occur when the ganglia are completely extirpated; but Eckhardt does not say whether it does or not, and therefore Cyon determined to perform this operation, and thus test the truth of Eckhardt's theory. When he cut through the last cervical or the first dorsal ganglion, he found, like Eckhardt, that diabetes was produced; but it occurred just as certainly when both ganglia, or even the last cervical alone, were cut completely away, or when the nerve-fibres entering this ganglion were all cut through, although the ganglion itself was never touched. This clearly

showed that Eckhardt was wrong, and that the diabetes occurring after operations on the last cervical or first thoracic ganglia was due to paralysis of the nerves which were connected with them, and not to irritation of the ganglia themselves. He next ascertained that all the fibres entering these ganglia had not the same effect in causing diabetes, for it occurred when either the branches which pass along the vertebral artery from the spinal cord to the last cervical ganglion, or the two fibres which connect it with the first thoracic ganglion, were divided, whereas section of the other nerves proceeding from the ganglion did not do so. It thus became evident that the nerve-fibres whose paralysis causes diabetes, come from the spinal cord through the vertebral nerves to the last cervical ganglion, and pass from it to the first dorsal in the two connecting branches which, in their course from one ganglion to another, enclose the subclavian artery, and form the annulus of Vieussens. So much having been ascertained, it would seem easy enough to trace the nervous path down the gangliated cord and splanchnics to the liver; and one would expect that, by dividing the cord in the thorax, and thus paralysing the fibres going to the liver, diabetes would be produced as certainly as when they were divided at the level of the vertebral artery.

Such, however, was not the case; for not only did subcutaneous division of the gangliated cord between the tenth and twelfth ribs not produce diabetes, but, if the cord were cut before, or at the same time as the last cervical or first thoracic ganglion, the diabetes which would otherwise have occurred did not appear. But when diabetes was first produced, division of the cord did not diminish it, or even hinder its increase, just as Bernard had found with regard to the splanchnics. In order to explain this apparently contradictory result, Cyon set about investigating the way in which the fibres of the annulus of Vieussens affect the liver, and more especially the circulation in it.

On irritating these fibres, he found that a number of fine white lines appeared round the lobules of the liver, in the position occupied by the small branches of the portal vein and hepatic artery; and these were so numerous as to produce the appearance of whitish spots on the organ, which continued while the irritation lasted, and disappeared after it ceased. At the same time that these spots appeared, he noticed that any cut or tear in the liver bled less freely than before. This indicated that contraction of the portal vein or hepatic artery, or of both, had been occasioned by irritation of the annulus; but, in order to make assurance doubly sure, as well as to find out whether it was the artery or the vein that contracted, he put a T-cannula into the hepatic artery, and connected it with a manometer. On then irritating the annulus of Vieussens, the pressure rose in the manometer as much as thirty to seventy *millimètres* of mercury; while in the carotid it only rose five to ten *millimètres*. To remove the last objection which might be raised, and show conclusively that the rise of pressure was due to contraction of the branches of the hepatic artery in the liver, and not to any other cause, he compressed the artery beyond the point where the cannula had been inserted, so that no change in the calibre of its branches could have any influence on the blood-pressure in its trunk. On again irritating the annulus, he found that no alteration in the pressure was produced. Division of both annuli produced, as was to be expected, dilatation of the branches of the hepatic artery, and fall of the blood-pressure in it. When the portal vein was experimented on in the same manner, the pressure only rose ten or twelve *millimètres* during irritation; and he thinks this is probably due indirectly to the change in pressure in the artery.

These experiments completely prove that the vaso-motor nerves of the hepatic artery are contained in the annulus of Vieussens; that their division causes the vessel to dilate, and at the same time produces diabetes. The theory of Bernard, that the diabetes depends on the dilatation, and on the consequent rapid circulation of blood in the liver, is thus rendered in the highest degree probable. But why should section

of the splanchnics or of the gangliated cord prevent the production of diabetes, but not remove it when present? This Cyon also explains. These parts of the nervous system contain the vaso-motor fibres for the vessels of the intestines; and, when they are cut, the vessels dilate, and blood accumulates in them to such an enormous extent that there is either too little blood remaining, or it is under too low a pressure for the circulation in the liver to become increased above its normal, even although its vessels be dilated. When the hepatic vessels, however, are dilated first, the blood continues to pass through them, and diabetes continues, even although the intestinal vessels have become relaxed.

The researches of Cyon, along with those of Bernard, render our knowledge of the part which the nervous system plays in influencing the production of sugar in the liver, and in causing diabetes, in so far as this disease depends on increased formation and not on diminished combustion, tolerably clear, though still incomplete; and enables us to form some kind of idea of the manner in which opium and allied remedies prove beneficial. The irritation which the inspired air produces on the ends of the vagi in the lungs is conveyed up these nerves to the medulla oblongata, and there exerts an inhibitory action on the vaso-motor nerves of the liver. When the irritation is increased, as by galvanising the vagi, the inhibitory action is so great as to produce complete paralysis of the vaso-motor nerves, and induce diabetes; and, on the other hand, when the vagi are cut, the vaso-motor nerves act more powerfully, causing the vessels of the liver to contract, and the production of sugar to diminish, as Bernard found that it did. It seems, therefore, not improbable that the beneficial action of opium and its alkaloids is due to their lessening the excitability of the vagus. We can hardly suppose, however, that diabetes is not sometimes due, either in whole or in part, to diminished combustion; and the causes of this still remain a matter for future investigation.

---

A SUBSCRIPTION is being raised among the medical profession in Italy, for the purpose of a medal in commemoration of the visit of Virchow to that country a few months ago.

---

AFTER great delay, Professor Bamberger, of Würzburg, has been appointed Professor of Medicine in the University of Vienna, in place of the late famous Professor Oppolzer.

---

THE Amussat prize has been awarded by the Academy of Medicine in Paris to Dr. Berenger-Féraud, for his treatise on ununited fractures and false joints.

---

THE *Philadelphia Medical and Surgical Reporter* learns, from good authority, that the abortion business is in such a flourishing state, that those who conduct it in New York City can afford to spend 150,000 dollars annually in advertising.

---

THE statement which has been circulated that Sir James Paget was summoned to attend the Prince of Wales in his illness, is erroneous. There have not been at any time in the course of the fever any complications requiring surgical assistance.

---

THE Royal Society of Natural and Medical Sciences in Brussels has elected Sir James Paget and Sir William Fergusson as honorary members. It has also conferred the same honour on Donders of Utrecht; Skoda, Hebra, Billroth, and Sigmund, of Vienna; Frerichs of Berlin; and Polli of Milan.

---

FROM a note communicated to the Academy of Sciences by M. Sainte-Claire Deville, and from some researches made by M. Renou, it appears that the November just past was colder in Paris than the corresponding month of any year during the past century, with four exceptions—1774, 1782, 1786, and 1858.

## THE WATER AT SANDRINGHAM.

THE water of the wells at Sandringham has this week been subjected to examination by chemical experts; and it is understood that the fullest examination of all the drainage and sanitary arrangements will be instituted. It was from the first intended that it should be so. The water was examined chemically three years since; and the report was then satisfactory. The subsequent arrangements have been carried out by highly qualified and skilled persons; but they will be subjected to re-examination.

## LONDESBOROUGH LODGE.

OWING chiefly to an unfortunate defect in the memory of the contractor, who, subsequently to the Prince's visit, was actively engaged with a full staff of workmen in examining, repairing, and ventilating the drains and cabinets at Londesborough Lodge, at the time of the visit of our commissioner, a somewhat unsatisfactory controversy has occurred as to some of the details in our report. The plan of the cesspool of which Mr. Peacock, the contractor, has since impugned the existence, was drawn on the spot at which he described it to exist, under his own eye, in Dr. John Murray's note-book. Some of the details in connexion with it are added in a pencil-sketch, drawn by Mr. Peacock's hand, on the same page. The written authority which Lord Londesborough courteously and candidly gave for the examination conducted on our behalf was at the same time placed in his hands in the presence of two other persons. His subsequent communications are curiously inconsistent with these facts. If any further investigation be at all needed, it had better be conducted by an official medical inspector of the Local Government Board.

## POISONED BY SEWER-GAS.

MR. WILLIAM ALLISON of East Redford writes to us as follows, *à propos* of the baneful effects of pent up gases, on their escape after concentration. "Many years ago I attended the members of a household, each of seven or eight of whom were feverish, but differently affected. Near a large country house, a bank of earth had been made and planted with shrubs, over a drain from a kitchen sink-stone (to hide the back premises; and, we may presume, the roots of shrubs had grown into the sough and blocked it). The bank was burst open by the expansion of strong foetid gas, which escaped from it and affected the air through the entire house, the windows of which were open during the daytime in close, hot weather. Of three servants with simple continued fever, one had a quinsy, and two deeply ulcerated throats. Of the family, all had fever and spurious rashes. The rash of a lady simulated measles; that of one child, scarlet fever; of two others, nettle-rash; of a fourth, an appearance of erysipelas; and all had ulcerated throats. They all began to sicken within a week of the escape of the gas, and I could not attribute their illness to any other cause."

## THE TEETH AND MOUTH IN IDIOTS.

In an instructive paper recently read at a meeting of the Odontological Society, Dr. Langdon Down insists on the importance of an examination of the mouth and teeth of idiots as a means of determining whether the idiocy is congenital or acquired. An abnormal formation of these parts indicates that the affection is congenital. The lips, especially the lower, are usually thick; they are often deficient in prehensile power; the mucous membrane is very liable to chronic inflammation, and to ulceration from very slight pressure; and the mucous and salivary glands are usually hypertrophied. The first dentition is almost invariably postponed; sometimes it is attended with no disturbance of the general health, sometimes with violent convulsive attacks. The milk-teeth are frequently dark and speedily become carious; and their stunted growth is often rendered more stunted by incessant grinding, which is very common in idiotic infants. The second dentition is accompanied often by epileptiform convulsions, which may have remained in abeyance from the completion of the first dentition, and may again, when the second dentition is completed, again be suspended until puberty. The evolution of the permanent teeth is

often postponed, and the sequence is slightly irregular. They are often crowded, so that sometimes the sides are presented. They are often arranged in different planes; sometimes the canines, sometimes the incisors, are most prominent. The enamel is imperfect, giving a honey-combed appearance, and they speedily decay. Dr. Down has been able to discover among the feeble-minded very few examples of the syphilitic teeth described by Mr. Hutchinson; and he considers this state to be quite distinct from the honeycombed teeth which he describes. The tongue is often unusually large; being elongated and deficient in muscular tonicity and co-ordination. The surface is often corrugated; and the papillæ are hypertrophied, producing roughness. The condition of the palate is of most significant value. From a very large number of measurements, Dr. Down finds that, with a few exceptions, there is a marked narrowing of the distance between the bicuspid in the two sides, with a consequent inordinate vaulting of the palate—the line of junction of the palate-bones occupying a higher plane. In the exceptional cases, the palates were wide in excess. The posterior part of the hard palate is often deficient, so that the soft palate hangs down abnormally. Cleft palate, in Dr. Down's researches, did not occur in more than five cases in a thousand.

## SMALL-POX AND VACCINATION IN HAMBURGH.

SMALL-POX has been raging fearfully in Hamburg lately. The following are the official statistics with which we have been furnished. They indicate, as usual, the great extent to which vaccination, even when imperfect or partially worn out, protects from death and modifies the disease, in the cases where, from want of complete or recent vaccination, it has not afforded an entire immunity. The numbers are: vaccinated, recoveries, 2954, deaths, 347; unvaccinated, recoveries, 10, deaths 700.

## CONDURANGO.

AT a recent meeting of the Aerzlicher Verein in Vienna, Dr. Schroff stated that the result of experiments made there with the alleged specific for cancer—condurango—had shown it to be quite worthless, as our English trials have already proved it to be. The Austrian Government had purchased a quantity of this supposed remedy, at a high price, for the purpose of having its effects tested in the Rudolf Hospital.

## EPIDEMIC DISEASES IN VIENNA.

VIENNA is under an evil epidemic influence. The deaths from small-pox, scarlet fever, measles, and diphtheria, showed in each case a marked increase during the ten days from November 29th to December 8th, as compared with the preceding ten days: The numbers were—small-pox, 22 (against 19); scarlet fever, 20 (against 14); measles, 14 (against 11); and diphtheria, 16 (against 10). It was not, however, known whether there had been an increase of the total number of patients suffering from each disease. In the three large hospitals, there had been a daily average of seventy small-pox patients, instead of fifty-two as in the previous period of ten days.

## WELL-DERIVED.

WE have lately had occasion to notice the very ungenerous and almost illegal conduct of the Warminster guardians, who declined to allow a superannuation pension to their medical officer Mr. Grubb, on the scandalous ground that they did not desire to establish a precedent. A few days since, Mr. Grubb was agreeably surprised by receiving from the vicar of Warminster and another gentleman the following letter, enclosing bank-notes to the value of £200.

"Dear Mr. GRUBB,—We beg you will kindly do us the favour of accepting the accompanying bank-notes, as a token of the deep sense we entertain of your untiring and devoted attention to the sick poor of this and neighbouring parishes, for the long space of twenty-seven years, and also of our true regard and esteem for you as a friend and neighbour. We heartily trust that your health may ere long be thoroughly restored, and that you may be spared for many years to come to your family and friends. Signed in the names of the contributors,

"JAMES ERASMUS PHILLIPS,  
"JAMES CHAPMAN."

"Dec. 11th, 1871.

## TYPHOID FEVER.

THE following resolutions have been passed by the Weekly Board and Medical Committee, on the occasion of the lamented death of Dr. Davidson from typhoid fever, contracted at the hospital in discharge of his duties.

"The Medical Committee desires to express its great regret at the death of Dr. John Davidson, late House-Surgeon and Resident Physicians'-Assistant, whose intelligence, devotion to duty, high principles, and amiability, won the esteem and respect of the whole staff."

"The Weekly Board desire to record how cordially they unite with the expression of sympathy with the Medical Committee at the death of Dr. John Davidson, and their thorough appreciation of his most excellent character and services."

## THE CONCOURS IN FRANCE.

A COMPETITION by *concours* for the office of surgeon to the Charité Hospital at Lyons commenced on December 4th, and lasted four days. There were six candidates—Drs. Aubert, Christôt, Fochier, Leriche, Magnien, and D. Mollière. The subjects of competition were: 1. A lecture of twenty-five minutes' duration on the anatomy and physiology of the hand; 2. A description of the influence of pregnancy on traumatism, and the influence of traumatism on pregnancy; 3. A description of erectile tumours, and ligature of the femoral artery in its lower third; 4. A written account of a clinical case (traumatic lesion of the elbow in a child); 5. A clinical lecture on the case of a child aged 12, who had pes valgus, and had been admitted into hospital in consequence of the foot having become painful. The contest, which appears to have been a very close one, ended in favour of M. Fochier.

## SMALL-POX IN PHILADELPHIA.

SMALL-POX has been prevalent in Philadelphia. The reports received at the Health Office show the following as the number of cases during the months named: July, 15; August, 58; September, 110; October, 942. In the October statement, only three weeks are included. The reports for the last week of the month, however, showed that the disease is decreasing. The following statement shows the number of deaths from small-pox in the city during the years stated: 1860, 57; 1861, 758; 1862, 264; 1863, 171; 1864, 260; 1865, 524; 1866, 144; 1867, 48; 1868, 1; 1869, 6; 1870, 9; 1871, 198. One hundred and fifty-three deaths from small-pox occurred in Philadelphia during the week ending November 25th, being an increase of twenty over the number in the preceding week.

## THE SUBORDINATE MEDICAL DEPARTMENT OF INDIA.

WE learn with pleasure from the *Indian Medical Gazette* that an attempt is being made to form a fund for the benefit of the widows and orphans of the subordinate medical officers in Bengal. A fund of this kind was formed twenty years ago, but perished from want of government support. Attempts have since been made to revive it, but without success. The present attempt, it is hoped, will be successful. It is said that there is every reason to hope that the Government will give its support. Dr. Francis, Deputy Inspector-General of Hospitals, is President of a Committee sitting at Dinapore for the purpose of discussing the means of forming and maintaining the fund. An actuary in Calcutta has been consulted for the purpose of calculating tables of subscriptions and payments.

## PRACTICAL GRATITUDE.

It is not often that we hear of such a display of gratitude on the part of a patient as one which has lately occurred to Dr. McIntyre of Odiham, an old and esteemed member of our Association. Twenty-five years ago, Dr. McIntyre operated on a lady for the relief of femoral hernia; and some years afterwards relieved her by his surgical skill of another troublesome malady from which she suffered—thereby enabling her to live in comparative comfort for twenty years. Her death took place a few weeks ago. In her will she appointed Dr. McIntyre one of her executors, with a legacy of £100; and also bequeathed to him

£4,000 "in testimony" (in the words of the will) "of his great kindness and professional services". Such an expression of gratitude and good feeling is creditable to both parties concerned.

## "CORNER FOR THE CURIOUS."

DR. SAUNDERS of Exminster writes to us: "It has often occurred to me that a 'Corner for the Curious' might be set apart in the JOURNAL, in which might be found bibliographical references to the old and often much forgotten medical literature of subjects brought from time to time before the medical world, such as the history of an operation, or the ideas which have prevailed at different times as to the nature of a particular disease. Medical antiquarian jottings and notes of medical superstitions, as they crop up in different parts, might here also find a suitable place." We shall be glad to see this idea take take root. It is not altogether a novel one, and there are difficulties in carrying it out. For the success of such an archæological corner, we need the spontaneous contributions of our readers. There are amongst our members such men as Dr. Aquilla Smith of Dublin, Dr. Greenhill of Hastings, Dr. Diamond of Twickenham, and no doubt many others, who from among their accumulating stores of quaint and curious erudition might enrich the medical stores of historic notes. To endeavour to vitalise the suggestion, we shall make in an early number a sort of beginning which will illustrate the possibilities of such a corner; and we shall be very glad to find that medical workers will fill this corner with chips from their workshops.

## THE CHOLERA.

CHOLERA has broken out at Medina, and between September 21st and October 4th (twelve days) 773 deaths took place; all the caravans from Medina to Mecca were consequently compelled to perform quarantine before being allowed to enter the latter city. Cholera is now, however, reported to be present in Mecca; and though Jeddah is yet free from the disease, all arrivals from that place are treated as if it were suspected of cholera. A cholera death is reported at St. Jean d'Acre in a passenger from Constantinople. Cases have also occurred at Samsoun (though not since November), at Galatz (which is stated to be in a bad sanitary state), at Amol, a place in the neighbourhood of the Caspian Sea, and at Astrachan.

## THE HUNTERIAN MUSEUM.

MR. ERASMUS WILSON has just purchased, for a large sum, and presented to the Museum, a fine specimen of the *Berardius Arunxii* of Duvernoy. This is a very rare animal, of which only four other specimens have been seen, all on the coasts of New Zealand. In 1862, an animal, conjectured to have been a *Berardius*, was embayed in Poriura Harbour, and was converted into oil. In January 1870, another was taken in Worser's Bay, near Port Nicholson; and the skull and a few bones were preserved for the Wellington Museum. Lastly, a specimen of this fine animal, which is thirty feet long, and, after *Hyperoodon latifrons*, the largest of the cetacea, ran aground on the beach near New Brighton, Canterbury, in December 1868. It fortunately came under the notice of Dr. Julius Haast, F.R.S., Curator of the Museum at Christ Church; and, on Professor Flower drawing Mr. Wilson's attention to its great rarity, and expressing a desire to have it for the College Museum, a check was at once given for the amount.

## NEW ROOMS FOR PATIENTS AT THE LONDON FEVER HOSPITAL.

WE have had the pleasure of inspecting the new rooms provided for the accommodation of private patients at the London Fever Hospital yesterday, and are glad to find the arrangements all that could be wished. The wards which previously accommodated eight patients have been divided into two large and handsome rooms, each intended for one occupant. The furniture is plain, but substantial and neat; there are short strips of carpet for each side of the bed, a few chairs, a table, looking-glass, and marble-top wash-stand. The roofs are high, and the rooms well ventilated, not only by the doors and

windows, but by traps in the side walls or roofs. A bath-room and water-closet are attached to each two rooms, exclusively for the use of the two patients. It is proposed to open at first four rooms for ladies, and four for gentlemen, and each is to be charged three guineas weekly for board and attendance. One of the long general wards on each side of the hospital is now to be divided by a partition—the convalescent and mild cases to lie on one side, and the acute on the other. The principle of isolation is thus as far as practicable to be carried out. These wards are intended for the reception of patients recommended by governors and annual subscribers, and for working-men and their families, clerks, and tradesmen, who cannot find sufficient attention at home, or who wish the superior skill and management to be had at the hospital. These will obtain admission on payment of two guineas on entry, or one guinea weekly. The Committee of the hospital are assured that, in making provision for private patients, they meet an urgent public requirement, and they are prepared to extend the accommodation should the demand for an extension arise.

#### CHRISTMAS IN HOSPITAL.

WE are most glad to find that the preparations for rendering this season as happy as possible to the inmates of the London hospitals are not behind those of former years, but rather excel them. In all the hospitals, such patients as can eat roast beef and plum-pudding will be welcome to a handsome quantum for dinner, with some fruit, and an excellent special "tea." In St. Thomas's, Guy's, and King's, the wards are to be profusely decorated with evergreens and mottoes. Dissolving views are to be shown to the patients of Guy's and St. Thomas's; and the little sufferers of the Hospital for Sick Children are to have a similar treat if they can be brought to see them. A children's Christmas-tree is to form a prominent source of pleasure in the Middlesex, St. Thomas's, and Sick Children's Hospitals. In Guy's, through the special efforts of the students and well-wishers, an entertainment by the "Apollo Minstrels" is to be given, and singing in the wards is to be generally allowed, and a prolongation of visits of friends. All the officers of the different hospitals happily seem to recognise the desirability of doing all that may prudently be done to make "Christmas in hospital" as pleasant to the patients as possible, compatibly with safety to their lives and progress to recovery. Mrs. Priestley, who is this year out of England, will be much missed at King's.

### SCOTLAND.

#### EDINBURGH ROYAL INFIRMARY.

THE managers have made an excellent selection in Surgeon-major Fasson for the appointment of Superintendent of the Royal Infirmary. From his long experience at the Herbert Hospital, Woolwich, and elsewhere, Mr. Fasson is highly qualified to fulfil the duties of the office.

#### GLASGOW MATERNITY HOSPITAL.

WE have simultaneously received the Thirty-seventh Annual Report of the Glasgow Maternity Hospital, and a Glasgow paper containing some rather serious complaints against the subordinate officials of that institution. The former states that, during the past year, 1,011 women participated in the benefits which the hospital confers; the number of women confined in the hospital having been 313, and at their own homes 698. The hospital has been very free from disease, which, moreover, has been mostly of a light character. But the interesting and instructive fact in the history of the hospital during the year is that relating to the occurrence of puerperal fever. The number of patients treated at their own homes amounted to rather more than double the number of those treated in the hospital; and five deaths from puerperal fever occurred amongst the former, while only one death from that cause took place in the wards of the hospital. The experience of this hospital for several years past, the reporters (Dr. J. G. Wilson and Dr.

Tannahill) go on to state, seems to prove that, by the systematic and rigid observance of complete segregation of cases of puerperal fever, perfect cleanliness, thorough ventilation, daily fumigations with carbolic acid and chloralum, and other measures, puerperal fever may be prevented from becoming epidemic in small lying-hospitals. These are important facts in the history of this lying-in charity, and should receive due attention from those who, in the question which was recently debated by the late Sir James Simpson and others, advocated home treatment, and who proposed to sweep away institutions of the kind. The complaints referred to, in connexion with the hospital, appear to have had their origin in the refusal of the matron to admit a woman who lay at the door of the hospital at three o'clock in the morning, on the point of confinement. The patient, it would seem, had threatened puerperal convulsions; and the medical gentleman in attendance had, in anticipation, made some previous inquiries regarding her admission into the hospital. While lying on the pavement, and after several attempts for admission had been made by the medical man in behalf of the woman, she was confined. It was only after the assistance of the police that the woman and child were then admitted. It is urged that the matron did no more than carry out her instructions by refusing the admission of the woman, the hospital having already its full complement of ten cases of confinement. Besides, no definite arrangement had been made for the admission of the patient. This may be so far true; but, in the circumstances of the case, the matron's conduct seems to require further explanation, especially when it is alleged that there were several empty beds in the hospital at the time.

#### THE RIGHT HON. ROBERT LOWE AND EDINBURGH UNIVERSITY.

A CONTROVERSY is being carried on in the *Scotsman* regarding certain statements made by Mr. Lowe, in his speech at Halifax on December 4th, as to the superiority of the London to the Edinburgh Medical degree in medicine. The examination in the Edinburgh College, he remarked, may be easily passed, but numbers of candidates prefer to come to pass the more severe examination imposed upon them by the London University. This statement has naturally irritated the Edinburgh professors; and Mr. Turner comes forward to vindicate his University—we need not say, with success. The substance of his letter is simply that Mr. Lowe's statement is not founded on fact, and is calculated to misrepresent and seriously injure the Edinburgh School of Medicine. He gives an analysis of the examinations in the Edinburgh University and the percentages rejected, from which it is seen that in the first and second examinations, nearly one-third of the candidates are rejected; and, though the ill-prepared and less industrious students are thus eliminated, yet even at the final examination as many as eight per cent. are remitted. He points out that an analysis of the *London University Calendar* shows that of the 539 graduates in medicine and surgery of that University, only eight received their medical education in Edinburgh; and of the 503 medical undergraduates, only six have studied in the Edinburgh Medical School. Mr. Turner further states that, during the five years in which he acted as Examiner in Anatomy in the University of London, only two Edinburgh candidates appeared before the Board. It has been stated by one of our contemporary's correspondents that the London University degree necessarily stands higher than the Edinburgh, inasmuch as the London examiners are not the teachers of the men who pass, whereas the Edinburgh examiners are also teachers. But the same may be said to a large degree of the London University. The great bulk of its medical examiners are teachers in University and King's Colleges, London, and in the hospital schools of the metropolis, which supply most of the medical graduates of the University. Moreover, the universities of Scotland have the advantage of having official examiners associated with the professors. If it be an evil to have the teachers of the schools also the examiners for degrees, it is to be found in the London University as well as in that of Edinburgh. The University of Edinburgh holds justly a very high position among the medical qualifying bodies of this kingdom.

## IRELAND.

## DEATH OF DR. MAYNE FROM SMALL-POX.

DR. ROBERT ST. J. MAYNE, Surgeon to the Meath Hospital, died on Saturday last of small-pox, after a few days' illness, at the early age of 28. He contracted the disease in the performance of his hospital duties. It was in his case accompanied by purpura, and combined with a rash much resembling scarlatina. Renal hæmorrhage seriously complicated the case. Dr. Mayne had not been revaccinated.

## CHARGE AGAINST A DISPENSARY MEDICAL OFFICER.

DR. BRODIE, Poor-law Inspector, has held an investigation into the charge of neglect of duty brought by Mr. O'Flaherty, Lisdon, Tuam, against Dr. French, Medical Officer of the Headford Dispensary District. The facts brought out after a long inquiry were, that Dr. French was engaged at a dangerous midwifery case, when a red ticket was sent to his house summoning him to attend a poor man named Murphy. He was not informed, on his return home, that the case was urgent; and early next morning a messenger was sent again. Dr. French attended after the dispensary hours. The man suffered from great prostration and pain, and died the same night. This dispensary district is 46,490 acres, or nearly 73 square miles, in extent. There is but one medical officer; no apothecary, nor midwife. The salary is only £136 : 16; and the number of tickets issued for the last year was 821. Of these, 304 were red or visiting tickets, and 517 black. Under these circumstances, unfortunately, cases will occasionally require the attendance of the medical officer at different places at the same time. The appointment of a resident apothecary in extensive districts would afford medical attendance in cases of emergency, which otherwise might prove fatal before the dispensary physician could attend.

## SMALL-POX IN DUBLIN.

It is stated, on a computation of cases that have come to the knowledge of the authorities, that seven hundred cases of small-pox existed in Dublin on Saturday last, December 16th. Owing to the difference of opinion as to revaccination which exists among the profession in Dublin, the public have not generally adopted this precaution. Very many infants have been found unvaccinated by the City Dispensary medical officers in houses, and even in rooms, and sometimes in the same beds, with persons suffering from the disease. The general rule in such cases has been to vaccinate all such unprotected children immediately; and this step has been generally followed by prevention or diminished severity of the disease. The law in Ireland permits the child to attain the age of six months before vaccination, instead of three as in England. "Waking" those dead, with the aptitude for taking the disorder engendered by sitting up all night in rooms offensive from the emanations both of the dead and of the living, and by the intemperance and irregularity of food in those celebrating this superstitious custom, has powerfully promoted the spread of small-pox, as it has before done in the case of cholera, fever, scarlatina, and measles. It is well, therefore, even now that the Roman Catholic Archbishop of Dublin has addressed his clergy (some of whom are reported ill of the small-pox) on the subject.

## THE DUBLIN OBSTETRICAL SOCIETY.

THE second meeting of this Society took place on the evening of the 16th instant. Papers on the subject of transfusion in cases of uterine hæmorrhage were read by the Drs. Ringland, senior and junior, detailing the particulars of two cases—the one fatal, the other successful—in which resort was had to this operation. A very interesting discussion took place, almost all the leading obstetricians of Dublin taking part therein. The instrument used in both instances was the invention of Dr. Robert McDonnell, and is to be commended at once for its efficacy and simplicity. It consisted of a glass pipette containing from six to eight ounces, ending in an India-rubber tube, to which is joined

a portion of glass tube; and this latter is connected by another portion of India-rubber tube to a piece of silver tube whose distal terminal opening is on the side, distant about an inch from its closed probe-pointed extremity. By this arrangement, security is afforded against the admission of air to the vein that is to be injected; for, the moment a bead of air is seen passing the glass tube, the nozzle of the silver tube can be withdrawn so far as to allow its escape outside the vein. Gravitation, aided, if need be, by forced expiration by the operator, is depended on for propelling the warmed and defibrinated blood into the opened vein of the patient.

## MEDICAL DECLARATION RESPECTING ALCOHOL.

IN the BRITISH MEDICAL JOURNAL of September 30th, we wrote as follows concerning the duty of medical men in relation to the temperance movement to the habitual and medical use of alcohol. "Looking to the ineffable misery and disaster, the waste, degradation, suffering, and crime, which are constantly wrought in this and most other civilised nations by drink, we are far from thinking that the importance of the subject can be exaggerated. The influence of medical men, if they were united and agreed, might be all powerful on this subject; and we should be glad to see a conference of medical men, including those of the highest class, originated in some really influential quarters, with a view to giving this subject a more thorough discussion than it has yet had. We should like to hear a discussion in which Parkes, Edward Smith, Hughes Bennett, A. P. Stewart, Paget, Jenner, and some of our leading provincial practitioners, would take part, in which the whole subject should be probed. To what extent, if at all, are physicians justified in recognising alcohol as an article of daily food in health? Does the habit of prescribing alcoholic drinks act injuriously upon the morals and welfare of the people? Is it possible or desirable to substitute the more enticing forms of alcohol by medicinal and less alluring forms? We all of us sympathise with the ends which the National Temperance League has in view. A small minority only practically participate in their means of action. Can we in any way, and in what way, help to rescue this nation from the curses which drink brings upon its population?" Consequent upon the publication of these observations, Mr. Rae, the secretary of the Temperance League, sought an interview in which to ask the advice of the Editor of this JOURNAL as to the best means of carrying out his suggestion. Mr. Hart sketched an outline memorandum, stating the points at issue, and recommended that Dr. Parkes of Netley, in the first instance, and other physicians and psychologists of eminence, should be consulted as to their views upon the subject. The result has been the framing of the subjoined memorandum, based upon the original sketch, under the revision of Dr. Parkes, Dr. Burrows, and others. It is a document of which the importance and interest are obvious, and we commend it to the careful consideration of the profession.

As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no medical practitioner should prescribe it without a sense of grave responsibility. They believe that alcohol, in whatever form, should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past.

They are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet; and, since no class of men see so much of its ill effects, and possess such power to restrain its abuse, as members of their own profession, they hold that every medical practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids.

Being also firmly convinced that the great amount of drinking of alcoholic liquors among the working classes of this country is one of the greatest evils of the day—destroying more than anything else the health, happiness, and welfare of those classes, and neutralising, to a large extent, the great industrial prosperity which Providence has placed

within the reach of this nation, the undersigned would gladly support any wise legislation which would tend to restrict, within proper limits, the use of alcoholic beverages, and gradually introduce habits of temperance.

George Burrows, M.D., F.R.S., President of the Royal College of Physicians; Physician Extraordinary to the Queen.

George Busk, F.R.S., President of the Royal College of Surgeons.  
G. E. Paget, M.D., D.C.L.Oxon., President of the General Council of Medical Education.

Thos. Watson, Bart., M.D., F.R.S., Physician in Ordinary to the Queen.

Henry Holland, Bart., M.D., F.R.S., Physician in Ordinary to the Queen.

Cæsar H. Hawkins, F.R.S., Sergeant-Surgeon to the Queen.

William Fergusson, Bart., F.R.S., Sergeant-Surgeon to the Queen.

Jas. Paget, F.R.S., Sergeant-Surgeon Extraordinary to the Queen.

Richard Quain, F.R.S., Surgeon Extraordinary to the Queen.

John Hilton, F.R.S., Surgeon Extraordinary to the Queen.

W. White Cooper, F.R.C.S., Surgeon Oculist in Ordinary to the Queen.

E. H. Sieveking, M.D., Physician in Ordinary to the Prince of Wales.

George D. Pollock, Surgeon in Ordinary to the Prince of Wales.

Thos. King Chambers, M.D., Honorary Physician to the Prince of Wales.

Henry W. Acland, M.D., F.R.S., Regius Professor of Medicine, Oxford; Honorary Physician to the Prince of Wales.

Arthur Farre, M.D., F.R.S., Physician-Accoucheur to H.R.H. the Princess of Wales.

George T. Gream, M.D., Physician-Accoucheur to H.R.H. the Princess of Wales.

Francis Hawkins, M.D., Physician to the Queen's Household.

T. Spencer Wells, F.R.C.S., Surgeon to Her Majesty's Household.

T. G. Logan, M.D., K.C.B., Director-General of the Army Medical Department; Honorary Physician to the Queen.

Thos. Longmore, C.B., Deputy Inspector-General, Army Medical Staff; Professor of Military Surgery, Army Medical School; Honorary Surgeon to the Queen.

J. Ranald Martin, Knt., G.B., F.R.S., Inspector-General of Hospitals; Physician to the Secretary of State for India in Council.

H. H. Massey, M.D., C.B., Deputy Inspector-General; Head of Sanitary Branch, Army Medical Department.

Thos. Crawford, M.D., Deputy Inspector-General of Hospitals; Head of the Medical Branch, Army Medical Department.

T. Graham Balfour, M.D., F.R.S., Deputy Inspector-General of Hospitals; Head of the Statistical Branch, Army Medical Department.

W. C. Maclean, C.B., M.D., Deputy Inspector-General; Professor of Military Medicine, Army Medical School, Netley.

E. A. Parkes, M.D., F.R.S., Professor of Hygiene, Army Medical School, Netley.

Wm. Aitken, M.D., Professor of Pathology, Army Medical School.

Wm. Johnstone Fyffe, M.D., Surgeon-Major; Assistant Professor of Medicine, Army Medical School.

And two hundred and thirty-seven other physicians and surgeons, mostly attached to metropolitan and provincial hospitals.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a meeting of the Council on Thursday, the 14th instant, the following business was transacted, in addition to the matters mentioned in the last number of the *BRITISH MEDICAL JOURNAL*.

The following resolutions of the Dental Board were approved and adopted by the Council.

1. That it be recommended to the Council that paragraph 10 of the Regulations relating to the diploma in Dental Surgery; viz., "10. Of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of dental surgery during two winter and two summer sessions"—be altered as follows, viz., "10. Of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of dental surgery during the period of two years."

2. That it be reported to the Council that, in the opinion of this Board, it is desirable that the diploma in Dental Surgery should bear the College arms, and that the diploma should be so altered in form as to admit of its being signed by the President of the College as well as by the Examiners.

3. That it be recommended to the Council that a ticket of admission to the Museum, to the Library, and to the College lectures, be presented to each candidate on his obtaining the diploma in Dental Surgery.

The following Report as to the wording and mode of issuing the general diplomas of the College was read and adopted.

That, in the opinion of your Committee, each of the several diplomas granted by the College should be issued on the direct authority of the Council, be signed, on behalf of the Council, by the President, or in his absence by one of the Vice-Presidents, and bear the College arms; and that the wording of each diploma should be altered accordingly.

It was resolved: That it be referred to the Committee to consider and report to the Council on the necessary alterations in the wording of the several diplomas, including the dental diploma.

The following resolutions, involving slight alterations in the draft scheme for an examining board for England were passed. That, in pursuance of the opinion of the Committees of the two Colleges, Clause X, altered as follows, be approved; viz., "That every matriculated student of an English university, who shall have completed the curriculum of study required by his university, and shall have passed such an examination," etc.

That, in pursuance of the opinion of the Committees, the suggestion of the University of London, that the nomination of Examiners should take place annually, be adopted, provided that the two corporations, the Colleges of Physicians and Surgeons, can legally give effect to it.

The following letter from Mr. Cock was read.

"Dean Street South, December 11th, 1871.

"My dear President,—Although my virtual retirement from the Court of Examiners took place at the last meeting, when I received such kind expressions of feeling from my colleagues as I can never forget, I believe it is right that I should inform you that it is not my intention to be a candidate for the next election.—Yours ever truly,

(Signed) "EDWARD COCK."

The President reported that the vacancy in the Court of Examiners, caused by the retirement of Mr. Cock, would be filled up at a special meeting of the Council in the ensuing month.

A correspondence with the Solicitor, on the subject of the oath hitherto administered to members of the Council and of the Court of Examiners on their accession to office, was read. The President stated that, in pursuance of the opinion of the Solicitor, a declaration in the terms proposed by him would in future be substituted for the oath.

Mr. Charles Hawkins, in pursuance of his notice, brought under the consideration of the Council the question as to the advisability of placing those who pass the examination for the Fellowship in classes according to merit; and, the Council having discussed the question, the subject was allowed to drop.

Mr. Gay, in pursuance of his notice, moved that the proportionately large number of rejections at the preliminary examinations for the diploma of the College was a fact which demanded the serious consideration of the Council, and that a committee be appointed to consider the subject and report thereon to the Council. The motion was seconded by Mr. Wilson.

It was moved as an amendment by Mr. Simon, and seconded by Mr. Erichsen: That it be a further reference to the committee appointed in December 1869 "to consider and report to the Council on the means offered to students entering the medical profession for passing examinations in general knowledge; to consider the causes of the large number of rejections which take place in the preliminary examinations of the College, and to report thereon to the Council." The amendment was carried, and Mr. Gay was appointed a member of the Committee.

Mr. Erichsen gave notice of the following motion: That, on the occurrence of a vacancy in any professorship or lectureship in the College, with the exception of that of Hunterian orator, due notice be given of such vacancy by advertisement in such journals and at such times as the President shall decide, and that candidates be invited to apply for such vacancy.

Sir James Paget, Bart., gave notice of the following motion: That it is desirable that, before proceeding to any nomination of members for election to the Fellowship under the fifth clause of the Charter of 1852, the Council should determine the conditions under which the election should take place.

Mr. Charles Hawkins presented a rare medallion of John Hunter by Tassi, and a bronze Brodie medal.

DR. ALFRED MEADOWS has been elected a Corresponding Member of the Gynecological Society of Boston.

## SPECIAL CORRESPONDENCE.

## LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

THE following cases and pathological specimens have been brought before the Medical Institution during the present session.

A Secondary Malignant Tumour of the Jaw of a middle-aged man appeared about two years after the removal of epithelioma of the lip, and grew with alarming rapidity. It was adherent to the bone, and passed down as far as the great cornu of the hyoid. Its removal by Mr. Bickersteth involved carrying away a large portion of the lower jaw, and a careful dissection of the tumour and infected glands from over the carotid artery and jugular vein. In connexion with this case, Mr. Harrison noticed a case of removal of a large fibro-plastic tumour from the neck, at which he assisted, where the internal jugular vein was severed. Its cut ends were promptly tied, and no ill effects resulted. He noticed also a case of wounding and subsequent ligation of the axillary vein, without any ill consequences. Not many years ago, injury to such large veins during an operation would have been deemed almost certainly fatal.

Mr. Bickersteth has performed Excision of the Wrist in seven cases, after the method introduced by Mr. Lister, with very satisfactory results, useful hands having been preserved. The important point in the after-management of the limb was the use of a splint reaching not further down than the palm of the hand, by which perfect rest to the sawn ends of the bones was secured, while daily movement of all the joints of the fingers was kept up.

A communication on Obstruction of the Lacrymal Passages was made by Mr. Shadford Walker, in which he deprecated the indiscriminate use of Weber's probe and Stilling's knife, by which the delicate structures of the canal, he said, are liable to be extensively lacerated. In chronic cases especially, he preferred careful probing of the passage, to produce gradual and permanent dilatation. The knife should be applied with caution, and only to those parts where the stricture is firm, limited in extent, and of old standing, or where the canaliculus and puncta are either obliterated or greatly narrowed, while the general state of the canal is but little below the healthy standard. As aids to the instrumental treatment, the application of a solution of alum or zinc by means of a long cannula-syringe directly to the part, followed by weak mercurial ointment, was recommended.

Dr. Turnbull narrated the case of a female patient under his care in the Royal Infirmary, suffering primarily from (Edema of the Left Leg, having all the appearance of Phlegmasia Dolens. After admission, an aortic murmur was discovered. Subsequently, pneumonia of the left base occurred, from which the patient was recovering, when the right apex was affected, and she died. On *post mortem* examination, the aortic valves were found fringed with soft prominent out-growths, one of which seemed to have been knocked off, there being a raw surface, with sharp ulcerating edges. It was supposed that this vegetation, detached from the aortic valve, had caused plugging of the iliac vein.

A very interesting paper on Hay-Fever was read by Dr. Davidson. It was illustrated by a history of a well marked case, in which the chief causes of the fits of sneezing were sunlight, growing hay, or any kind of luxuriant grass, a warm moist atmosphere, or any overheating of the body or head. The chief means of alleviation were: 1. Keeping in the dark or under shade during the brightness of the day; 2. Hill or sea breezes; 3. Whatever promoted a comfortable general circulation through the body. Two or three minutes' swim in the sea generally removed the symptoms as if by magic. The principal theories advanced to account for the irritation in hay-fever were described as being as follows. 1. The mechanical theory, which attributes the irritation to the pollen of hay and grass floating in the atmosphere, and coming into contact with the mucous membranes of the eyes, mouth, and throat. 2. The chemical view, that heat volatilises the benzoic acid which is known to be a constituent of some grasses, and which thus is inhaled, and sets up the coryza. But, although the vapours of benzoic acid are irritating, they are not more so to hay-fever subjects than to others. 3. The vital theory, first advanced by Helmholtz, which attributes the disease to the formation of vibriones in the nasal passages from the emanations from the hay. Infusions of hay are a ready source for obtaining vibriones; and a microscopical examination of the secretion of the nose during the disease had shown peculiar bodies to exist.

In a note on Psoriasis Palmaris, Mr. Edgar Brown contended that the affection thus designated is not true psoriasis, but a local form of eczema.

A very remarkable case of abnormal foetation has occurred in the Lying-in Hospital. A woman, aged 33, the mother of two children, was brought in. She was pregnant, supposed to have gone a fortnight beyond term. A fistulous opening existed at the umbilicus, communicating with the cavity of the uterus, from which there was a copious discharge of horribly offensive dark fluid. The os and cervix uteri were not in the condition usual at term—the os being closed, and the cervix about its ordinary length. After dilatation with a tent, Condyl's fluid, injected into the os, escaped freely by the opening at the umbilicus. A tumour was felt in the posterior vaginal *cul-de-sac*, which gave the impression, as to size, form, and consistence, of a foetal head, quite unconnected with the uterus. The os and cervix were in the condition usual after artificial dilatation with tents; but, on passing the finger high up towards the fundus, the denuded cranial bones of a foetus could be felt. The parietal bones were separated, much as if perforation had been performed. The previous history of the case was very imperfect. The woman stated that she had been under medical care at the dispensary; that she had no vaginal discharge or other indications of labour; and that the opening in the umbilicus had existed for three days before admission. In consultation, it was decided that the condition of the patient called for immediate interference; and it was determined to enlarge the opening already existing at the umbilicus. This was accordingly done by Dr. Finigan, and a full-grown foetus extracted in an advanced state of decomposition. The ribs were quite denuded, and the two parietal bones lying detached in the cavity in the abdomen were removed subsequently. There was no trace either of a placenta or decidua. The umbilical cord consisted of about three or four inches of decomposed tissue. The cavity in which the foetus had been enclosed presented externally a perfectly smooth surface; its walls were very thin, and closely adherent for a considerable distance to the abdominal parietes. The patient rallied from the operation well, but succumbed in a few days. A *post mortem* examination showed the cause of death to have been peritonitis. The foetus had not been contained in the cavity of the uterus, which was about the size of the organ at the third month; but its walls, instead of being closed in alone by the fundus, were continuous with the cavity already described which contained the foetus, and appeared to have consisted of a gradual development of the tissue of the fundus, the result of interstitial extrauterine gestation; the ovum having probably passed into the structure of the uterine parietes, and there gone on to its full development. The tumour felt in the posterior vaginal *cul-de-sac* proved to be the ovary, occupied by a large ossific cyst, filled with pulsatious matter mixed with hair. The probable explanation of the absence of the placenta and decidua was, that these structures had undergone decomposition, and had escaped through the opening in the umbilicus, from which the discharge during life was profuse, and of an unusually offensive character.

The introduction of Australian preserved meat into some of the work-houses and gaols in this locality is said to have effected a very considerable saving in the cost of maintenance; and the meat is much relished by the inmates.

## VIENNA.

[FROM OUR OWN CORRESPONDENT.]

*The Pathological Museum of Vienna.*

OUR Vienna correspondent sends us the following interesting account of this collection.

The museum of pathological anatomy at Vienna is of no remarkable size, but contains some great curiosities, and every object in it is worthy of attention. On first entering, a case of calculi is seen in front. The vesical calculi present nothing very special; some of the renal calculi are of portentous dimensions—one, indeed, is as large as an ordinary kidney. Many have assumed the shape of the pelvis of the kidney and ureter, and resemble pieces of native coral. There are in a neighbouring case kidneys showing most complete hydronephrosis, and resembling bladders blown and dried. There are also some fine specimens of cystic foetal kidneys, where the kidney, from its size, presented an obstacle to delivery.

In another case, is a collection of skulls exhibiting the different injuries inflicted by lethal weapons in war, as sabre-cuts, bullet and shell wounds, etc. One skull had been so struck as to drive in the nasal bones and the interorbital portion of the frontal bone, but to no great extent. There is the usual array of skulls showing the ravages of syphilis, and others showing the fearful progress of some forms of cancer. Others have a mass of bony plates coming off from the skull at right angles, and constituting curious masses, at a little distance looking like "sea-urchins;" and some small ones projecting from the interior of the skull.

There are spines with the ordinary curvatures, and others illustrating

lordosis and scoliosis (Rokitansky), and so twisted that the ribs of one side spring from the opposite side of the mesial line. The absence of pelvic deformity when rickets is situated in the upper half of the body, and its presence when the legs are distorted, on which the late Sir James Simpson strongly insisted in his lectures, are well shown here. Even in spines with evidences of the most extensive disease the pelvis are of fair shape, and presented no obstruction to parturition. One spine is completely ossified from one end to the other by the substitution of thin bony plates for the intervertebral cartilages, so that the owner must not only have had a perfectly rigid spine, but must also have been distinctly diminished in height. In connection with spinal caries is a specimen of the cyst-like wall of a psoas abscess, with one large bladder-like distension within the abdomen, an isthmus under Poupart's ligament, and another large cyst below, the whole of very unusual dimensions, and dwarfing the one engraved in Miller's *Surgery*.

Some cases of rickets affecting the lower limbs are preserved, and in one the legs are so much curved, that the patient must have incessantly occupied a sort of Turk-like sitting posture. There is a skeleton showing exostosis of almost every bone, especially at the insertion of the muscles in the lower part of the femur and head of the tibia and fibula. There are, too, as might be expected, examples of curiously united fractures; and in one is a piece of the original bone, about one and a half inches long (a comminuted fracture), lying on the outside of an united bone, which is by so much shortened.

There is a capital specimen of reversal of the viscera, with the heart and spleen on the right side, and the liver on the left; a second, in course of preparation, will soon be added. There is one specimen of obstruction of the aorta at the ductus Botalli; not quite complete, however, the descending aorta being about as large as the external iliac, and the collateral circulation being established through the internal mammary and epigastric descending branches from the axilla to the gluteal vessels, and by most extensive and numerous anastomoses between the vessels of the muscles of the back. A companion to it in the shape of a similarly imperfectly obstructed vena cava ascendens, and development of a collateral venous circulation in a very much similar manner, is also of great interest.

There is a (probably) unique case of a ring through the vocal cords. A man was eating goose, and got one of the rings of the goose's trachea into his own larynx; here it excited inflammation on each side, till it became encircled by a hasp, if I may be permitted to use the expression, from each vocal cord, and there it hangs, a curiosity of no ordinary character.

The curiosities of foetal life are very interesting. There are several forms of united twins, both *en masse* and as skeletons. In two or three of the skeletons there is union of the sternum merely, and in another union of the sternum and the forehead. But even more curious still are the cases, three in number, where the union is by the head alone—one head and two entirely separate bodies. In one, the union has taken place so perfectly that there is one face, complete and symmetrical, formed by the left side of the face of the left infant, and the right side of the face of the right infant. But there is no vestige of the opposite sides of the faces to be discerned, and this symmetrical face is accompanied by two ears in front, and a second pair behind, with bulging occiputs. What difficulties they presented in parturition is not recorded; but it would have taxed the intellect of the late Sir James Simpson himself to lay down rules for the diagnosis of a head common to two separate bodies. Even more curious still is a veritable genuine Syren. There it is, with a human head and an united extremity, widening out at the tail, apparently by the distribution of the feet. The limbs which should have been found along with that head are wanting; the original vertebrae have apparently remained unchanged, and instead of a human trunk, etc., there is a fish-like continuation; and the feet, true homologues of the tail, still in their altered form the great means of progression, have gone back to their primitive form; not, however, in the vertical tail of the fish, but in the horizontal tail of the pinnigrade carnivora. The seal-like head and eyes, and fish-like trunk of that human form, are rendered still less human by injection for the purposes of observation. The wax cast which accompanies it and is of the colour of human skin, is far more atrophied than the original. Near it are other monstrous and misshapen infants, either by abnormal attachment of the placenta, or from excessive development of one organ, or atresia of another, of which, and of the highly interesting abnormalities and morbid conditions of viscera in the adult, some further account may some day be given.

At a public meeting at the Guildhall, Swansea, the Mayor in the chair, it was resolved to "build and establish a convalescent home for Glamorganshire and the adjacent counties," and an influential committee was appointed for the purpose of carrying the resolution out.

## ASSOCIATION INTELLIGENCE.

### BATH AND BRISTOL BRANCH: ORDINARY MEETING.

The second ordinary meeting of the session was held at the College Green Hotel, Bristol, on Thursday evening, December 14th, at seven o'clock; CROSBY LEONARD, Esq., President, in the chair. There were forty-two members and three visitors present.

*New Members.*—Mr. Louis J. King was elected a member of the Association and of the Branch.

*Cases.*—The following cases were read. 1. Successful Case of Severe Compound Dislocation of the Ankle-joint. By H. Cooper, Esq. 2. Case of Successful Staphyloraphy. By F. P. Lansdown, Esq. 3. Excision of Upper Jaw. By C. Steele, Esq.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, DECEMBER 12TH, 1871.

T. B. CURLING, Esq., F.R.S., President, in the Chair.

ON THE PATHOLOGY OF SCARLATINA, AND THE RELATION BETWEEN ENTERIC AND SCARLET FEVERS. BY JOHN HARLEY, M.D. LOND.

In the first portion of the communication, the author treated of the morbid anatomy of scarlatina, and gave the details of twenty-eight cases of his own observation. Of these, the greater number died on days ranging consecutively from the third to the fifteenth; the remainder died on the seventeenth, twentieth, twenty-fourth, twenty-ninth, thirty-third, forty-first, and sixty-ninth days. More or less albuminoid and fatty degeneration of the kidneys existed in six of the cases, and these died on the fifteenth, seventeenth, twentieth, twenty-ninth, forty-first, and sixty-ninth days respectively; the kidneys were healthy in the remainder. The pathological changes common (with a few exceptions depending chiefly upon the time of death) to all the cases were as follows.

1. *The Formation of Fibrinous Clots in the Heart and Great Vessels During a Pyrexial Condition at any Period of the Disease.*—This was the commonest cause of death during the early stage. It was indicated during life by the reduction, often very sudden, of a full and bounding pulse of 120 to a dribble of 150 or 160 almost imperceptible impulses; and the failure of the heart's action was commonly attended with orthopnoea and delirium from obstruction of the pulmonary and cerebral circulation. On opening the body before it had lost a degree of temperature, and while the blood was hot and fluid, the right heart would be found distended partly with dark blood, which coagulated on exposure; and partly, sometimes chiefly, with a large, firm, white bifid clot, continuous through the auriculo-ventricular opening. Each portion was interlaced with and firmly adherent to the tendinous cords and muscular bands of the cavity in which it lay; and each portion sent a rope-like prolongation into the orifice of the great vessel connected with the cavity. These processes frequently were prolonged, in ramifications corresponding to those of the blood-vessels, into the cranial cavity, and into the lungs. These partial casts of the great vessels were often nine inches long, and occupied vessels of the sixth and seventh degrees of ramification.

2. *Marked Derangement of the Hepatic Function.*—The bile was examined in twenty cases. In five only was the secretion normal, and in these cases death occurred on the third, fourth, twenty-fourth, forty-first, and the sixty-ninth days respectively. In the remaining fifteen cases the bile was deteriorated. In two the coats of the gall-bladder were injected, and the mucous membrane rose-coloured. In the first of these cases there was a complete absence of bile, there being only a few drops of colourless alkaline fluid. In thirteen other cases the bile was greatly deficient in solid matters. The specific gravity did not exceed 1014, and the amount of solid matter in 1,000 grains in no case amounted to more than 36.4 grains. In one case there were only 11.1 grains of solid matter in 1,000 grains. In the majority of the cases the bile was turbid from epithelial debris, but on standing it became transparent, and resembled pale urine. In all the thirteen cases there was a notable deficiency of biliary acids, and in two a complete absence. The colouring matter of the bile was present in every case. If, as rarely happened, the bowel contained solid feces, it was of a pale ochre or sulphur colour. But the fecal matters were commonly fluid, grumous, or flocculent, often slimy, and of a pale ochre colour. Such, also, were the characters of the stools before death in many cases.

3. *General inflammation of the lymphatic glands* was present, usually confined to those of the neck, but occasionally extending to those of the extremities; of the spleen and mesenteric glands; and of the whole of the solitary and agminated glands of the alimentary canal, but commonly affecting only those of the fauces, and of the ileum and colon. These morbid appearances were remarkably uniform, and were observed in every case. The tonsils and solitary glandulæ of the tongue, and the external glands of the neck, were perceptibly affected in every case. In several cases large buboes formed in the neck; in three these were associated with diffuse cellulitis and purulent infiltration; and in one of these the popliteal and axillary glands and their surrounding connective tissue were similarly affected. In these cases the glands themselves were slow to take on suppurative action; and, although they were generally much enlarged and purple, comparatively few had softened centres. The spleen was enlarged in twenty-three cases, and in five of these it was increased to nearly twice its ordinary bulk. In two others it was not examined; and in the remaining two cases it was of the normal size. The mesenteric glands were swollen and inflamed in every case. In eight cases the mesentery formed a thickened, heavy, lobulated mass, and many of the glands were as large as walnuts or pigeons' eggs. Even the small glands in the attached borders of the transverse and descending mesocola were purple and turgid. The solitary glandulæ of the ileum were in a condition of psorentery—*i.e.*, forming white granular and more or less hard elevations, like a thick sprinkling of large sago-grains upon the mucous membrane—in fourteen cases. In six other cases, the solitary glandulæ were only partially affected, the swelling was more diffuse, the glandulæ being only moderately raised; but they were always deeply injected, and in some cases had an abraded appearance. In three cases, in which death occurred on the eleventh, seventeenth, and sixty-ninth days of the fever, there was only very slight swelling of a few of these glands; and in four cases, in which death occurred on the fifteenth, twenty-fourth, twenty-ninth, and thirty-third days respectively, the glandulæ were altogether unaffected. The agminated glands of the ileum were more or less swollen and inflamed in every case but one—that in which death happened on the thirty-third day. In one case (death on the seventeenth day from suppurating buboes in the neck), there was only very slight swelling. In all the other cases the results of inflammatory action were decided, and in many cases severe. The glands were commonly raised the eighth of an inch above the surrounding mucous membrane, than which they were always more deeply injected. In the greater number of cases the mucous membrane was generally pale, and sometimes thin and bare, while the agminated glands were of a vivid red or claret colour. The inflammatory action was usually confined to the glands in the lower third of the ileum, but in three or four cases the whole of the patches from the jejunum downwards were affected. In some of the larger glands isolated foci of inflammatory action were occasionally observed. The interfollicular ridges were often the eighth of an inch wide, giving to the paler glands a spongy appearance; but these ridges were as often vascular, with fine hair-like turgid vessels, and in some cases they were prolonged into folds a quarter of an inch in length. In two or three cases an almost bleeding gland had a softened abraded surface. The mucous membrane of the ileum was itself severely inflamed in two or three cases, and was covered by a thick adherent layer of white opaque mucus. The solitary glandulæ of the large intestine were enlarged and inflamed in eight cases. In one of these there was acute desquamation of the mucous membrane of nearly the whole of the bowel. In another case, the cæcum was severely congested. In those of the remaining cases in which the large intestine was examined, it was quite healthy.

On taking the above described pathological conditions into one general view, it appeared that there was an increase of fibrin in the blood during an attack of scarlatina, and that death was likely to occur during the first week from its deposition in the heart and great vessels; that the condition of the biliary function was such as to lead to an outbreak of diarrhoea, if this had not already happened; that a latent enteritis, sometimes general, but commonly only affecting the solitary and agminated glands, existed in a high state of development during the pyrexial stage of scarlatina, ready to declare itself openly upon very slight provocation; that this intestinal affection was only a part of a general lymphatic inflammation involving the whole of the lymphatic system, including the mesenteric glands and the spleen in one common action; and, further, that this condition might persist in some degree, either in the bowel or the mesentery, as late as the sixty-ninth day, and without any outward indication of its presence throughout.

From this view one general conclusion was inevitable—*viz.*, that the pathological changes accompanying an ordinary attack of scarlatina included all those of the first stage of enteric fever, and that the transition from one disease to the other was but a natural pathological

sequence, readily determined by any cause which might increase the intestinal irritation.

The proofs of this interchange, or sequence, constituted the second part of the subject, and contained accounts of several original observations.

The author next gave a series of cases to illustrate the coexistence of the two diseases; and he concluded by remarking that the interchange or sequence of scarlatina and enteric fever had been frequently noted, and always attributed to accidental coincidence. In his article on "Enteric Fever" in Reynolds's *System of Medicine*, he had expressed his convictions on this subject; and had thought of terming the contagious variety of enteric fever "abdominal scarlatina." He had abandoned the term then, because it had seemed that the evidence which he had adduced to show the close relationship implied in it was insufficient for conviction. Now, however, he submitted this term to the profession as a definite description of a disease which the practitioner would occasionally meet with. He would also ask his fellow-labourers to go one step further, and to discard those transcendental ideas of enteric fever which make of it a disease *per se*, and to open their minds to receive what nature would soon teach them—*viz.*, that enteric fever and all its attendant phenomena might occasionally become a part of almost any other more general inflammatory condition, specific or simple.

Dr. BROADBENT said that the Society was indebted to Dr. Harley for a very complete description of the pathology of scarlet fever. He could not, however, agree with all the views of the author of the paper. It was quite true that an attack of enteric fever often followed one of scarlet fever; but it must be remembered that the converse was sometimes the case, the two diseases overlapping each other in all directions. Not only did enteric follow scarlet fever, but scarlet fever sometimes followed enteric. He (Dr. Broadbent) had seen instances in which, during an attack of enteric fever, scarlet fever appeared, and ran through its course before the completion of the enteric attack; so that for a time there was a combination of the symptoms of both fevers—sore-throat and intestinal affection, rose-spots and scarlet rash. Their overlapping, and their occasional co-existence, indicated that the diseases were distinct rather than identical. There was no doubt a similarity in the pathological results of the two diseases; but there was this striking difference, that in scarlet fever, unless there were distinct evidence of a new attack, the disease stopped short of ulceration of Peyer's patches; whereas this occurred early in enteric fever. The affection of the lymphatic system in both diseases was no proof of their relationship, further than it showed that they were both blood-diseases.—Dr. SANSOM admitted the elaborateness of Dr. Harley's description of the pathology of scarlet fever; but he thought that much credit was also due to Dr. Fenwick, who had worked at this subject. He agreed with Dr. Broadbent that evidence as to the unity of the diseases was deficient. Another argument against the view of identity was in the difference of the causes; typhoid fever being propagated by emanations, scarlet fever by contact. It should be remembered that scarlatina raged most in localities where typhoid fever prevailed.—Dr. T. H. GREEN must hesitate considerably before being able to accept Dr. Harley's views. As to the pathological changes in the lymphatic glands, these occurred in other acute inflammatory conditions, especially in children.—Dr. JOHN WEBSTER could not think that scarlet and enteric fevers were identical. He asked whether a child suffering from scarlatina ever communicated enteric fever.—Dr. REGINALD THOMPSON said that there were two points of distinction in the clinical history of the two diseases. First, it sometimes happened that scarlet fever occurred in a choreic patient, and then the chorea became mitigated or removed; while, in two cases where he had seen typhoid fever occurring during chorea, the latter disease was not influenced. Secondly, rheumatism often followed scarlet fever, but was not known as a sequence of typhoid.—Dr. CHARLTON BASTIAN said that the facts brought forward by Dr. Harley tended to show the alliance between the pathological conditions of scarlet and of enteric fever. It was known that there was a general resemblance between the pathological conditions in fevers, and that there was a general tendency to affections of the lymphatic system. The evidence brought forward by Dr. Harley suggested the question whether the condition of system induced by scarlet fever might not favour the development of enteric fever. He saw no reason why the two conditions should not be interchangeable. The idea of the so-called specific nature of diseases was derived from the belief in the specific nature of animal and vegetable species; and if there were, as he believed, grounds for doubting the latter, our faith in the former must also be shaken. He rejected the notion of the origin of these diseases from germs, and regarded them as blood-diseases, modified by circumstances in various cases, and bearing a relation to each other much in the same way as certain diseases of

the nervous system, which are known to be interchangeable.—Mr. SAVORY asked, with regard to the affection of the lymphatic glands, whether all blood-poisons did not chiefly affect the organs concerned in the elaboration of blood. By the term specific, as he understood it, it was meant that the group or class to which it was applied was separated from others by certain well defined characters. Did cases occur in which it was difficult to say to which group a case belonged? Was there a hybrid between scarlet fever and enteric fever? He also asked whether the two diseases were mutually convertible—i. e., whether one gave rise by infection to the other.—Dr. JOHN HARLEY said that he had noticed cases of intercurrent of the diseases, such as had been described by Dr. Broadbent. He had examined the intestinal and mesenteric glands in typhus fever, and had not found them enlarged to any appreciable extent. The mesenteric glands were no doubt enlarged in the diseases of children. With regard to the relative contagiousness of typhoid and scarlet fevers, he thought that this property had been much overrated in respect to the latter disease. He thought that one of these diseases was capable of producing the other, as he had sometimes seen cases of enteric fever brought from houses in which several of the inmates were at the time suffering from scarlet fever.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, DECEMBER 16TH, 1871.

FLEETWOOD CHURCHILL, M.D., in the Chair.

*Fracture of Cervical Vertebra.*—Mr. EDWARD HAMILTON exhibited a specimen taken from the body of a man about 40 years of age, who had fallen through a height of sixteen or seventeen feet on his vertex. On being taken up, he was in a state of collapse; but was shortly able to give a detailed account of the accident. He was removed to Steevens' Hospital, where it was found that, from a line a little above the nipple, there was complete loss of muscular power, voluntary and reflex; loss of sensation; and there was also priapism. The skin was clammy, and the pulse below 40. Respiration was diaphragmatic. His head was drawn back in a state of opisthotonus. He was, however, rational and able to swallow. Next day, his pulse had risen to 70, and he presented a marked line of hyperæsthesia between the healthy and paralysed portions of his body. He died of asthenia forty-eight hours after the accident. On examination, the atlas was found to be comminuted, and the laminae of the sixth and seventh cervical vertebrae to be fractured, with displacement of the former, so as to compress the cord. There was no fracture of the skull, nor of the odontoid process.

*Stenosis of the Mitral Orifice.*—Dr. HAYDEN exhibited the heart of a lad aged about 18, who had been under his notice for the last four years. His illness dated from a fall from a cart, in which the pony trod upon his chest. He suffered at the time from pain in the chest and hæmoptysis, as well as dyspnoea, but was soon able to resume his duties as night-porter in a shop. Eight months after the accident, he began to suffer from sudden and severe attacks of dyspnoea. In a state of collapse from one of these, he was taken to the Mater Misericordiae Hospital. On examination next day, the lungs were found to be normal. There was a basic systolic murmur, not traceable into the aorta. The apex-beat was violent, and a præ-systolic murmur was here audible; the pulse, which was 150 on his admission, soon fell to 70. He soon improved. Before leaving hospital, the systolic murmur had vanished. On his second admission, he presented similar symptoms, with the addition of a reduplicated second sound. The symptoms remained the same throughout, the systolic murmur appearing and vanishing at intervals; the apex gradually approached the left side, considerably transgressing the line of the nipple. While in the hospital for one of his usual attacks, he took small-pox, and, during the course of the disease, he died suddenly. On the *post mortem* examination, the heart was found to be greatly hypertrophied. It weighed 18½ ounces. The left ventricle was of normal size, but the left auricle was enormously dilated and hypertrophied. The apex was bifid, owing to the hypertrophy of the right side. The mitral orifice was so contracted as hardly to admit the tip of the little finger.

*Primary Sarcoma of Mediastinum.*—Dr. BENNETT showed a specimen of a sarcomatous tumour situated in the anterior and middle mediastina, which he has met with in the dissecting room. The tumours appeared to have originated in front of the base of the heart, and to have extended inwards, so as to cause obliteration of the pericardium. It had invaded the heart-structure, and pierced the right ventricle in the front of its conus arteriosus. A mass projected into the right ventricle, close to the origin of the pulmonary artery, extending to its valves. Secondary growths occurred in the mediastinum, in the heart-tissue, in the root of the left lung, and in the wall of the œsophagus. These latter had so pressed the vessels of the left lung and pleura as to cause

great fluid effusion into the left pleural cavity, and complete compression of the lung. There was moderate general dropsy and ascites present, due to the impediment to the circulation. The tumour proved, on microscopical examination, to be scirrhus. There was no cancer elsewhere.

*Curious Head, Neck, and Trochanters of a Femur: Resection.*—Dr. BARTON exhibited a specimen of the head, neck, and trochanters of the femur of a child six years old. The child had been admitted into the Adelaide Hospital in the spring of this year, suffering from morbus coxae, then in its second stage. After admission, the condition of the child very much improved, but subsequently became much worse; and in July it became apparent that an operation would alone afford a chance of life. Excision was consequently performed, with success. The upper parts of the femur had undergone considerable absorption, so as to be hardly recognisable. The acetabulum was greatly flattened, but there was no dislocation.

## CORRESPONDENCE.

### PHYSICIANS AND HYSTERIA,

SIR,—I cannot but think that we ought to feel deeply indebted to Dr. Tilt for coming forward with such frankness to admonish physicians and surgeons of their shortcomings. No doubt the lines,

"O wad some power the giftie gie us,  
To see oursels as others see us,"

have inspired his mind with a compassionate feeling, and, like a true friend, he has supplied our want. Yet it almost seems to me as if his zeal had outrun his discretion; and, for my own part, I am obliged to set him right on some points where he labours under a mistake.

1. He affirms that I, in common with others, "own that I know nothing about diseases of women." I am really at a loss to know on what he bases this affirmation. I deny it absolutely, and beg to assure him that I am quite as capable of dealing with any ordinary case of so-called "female disease" as he is of managing a common bronchial catarrh. In fact, Dr. Tilt's assertion seems to me one of the most extraordinary that I have ever heard.

2. In his representation of my views of hysteria, Dr. Tilt does me again very scant justice. I take particular pains to distinguish two conditions, which are both very commonly designated "hysterical", and where the surface-phenomena may be very much alike. In one, I hold the disorder to be chiefly of the mind—in the other, of the body; and I endeavour to distinguish between the two. To the latter, suitable drugs are very beneficial; to the former, they are useless. I insist that it is unjust to regard these classes in the same light; and I prefer to reserve the term "hysterical" for those who need moral, and not material, remedies. The others should be regarded in the same light as sufferers from any bodily ailment. If Dr. Tilt will read from p. 468 to p. 480 of my work, I think he will admit that it is very far from being true that I look upon hysteria as always implying a surrender of the patient's will to temper and deception. But that there are many instances in which such is the case, no man of unbiased judgment and adequate experience can, it seems to me, well doubt.

3. With Dr. Tilt's statement that hysteria requires two factors for its production—(a) a predisposing nervous state, (b) the stimulus of some determining cause—I can in great measure agree. But I assign much more importance than he does to the predisposing nervous state, and to the mental condition, which is apt to be closely related to it. Given a certain state of nervous system, a slight determining cause will produce in a young woman an attack of hysteria, just as it often will in a young girl an attack of chorea. A mental perturbation will do it, or various small irritations. That ovarian and uterine irritations are very effective, I do not doubt; but I cannot help thinking that not a few of those "mildest forms of anæmic ovarian uterine disease", which Dr. Tilt deems so potent as causes of hysteria, are simply neuroses, expressions of the primary nervous diathesis, and not at all stimulants which call the hysteria into play. Surely, when a young female falls into the state of collapse which often attends the effort of development of womanhood, and becomes anæmic and amenorrhœal, and therewith hysterical—liable to hysterical prooxysms—it is quite too much to ascribe the hysteria to the amenorrhœa. Both have come from failure of power, and both disappear under a well managed tonic regimen; and for the most part, I think, the amenorrhœa is not the first to give way. Yet do not such cases as these swell the lists where hysteria is made out to be dependent on disorders of the genital organs?

4. While I quite admit that, in obscure and refractory cases, and in those where evident symptoms of internal disorder are present, a tho-

rough exploration of the pelvic organs should not be omitted, yet I submit that young females ailing with ordinary hysterical disorders—*maux des nerfs*—are about the very last persons whom a right-minded physician willingly subjects to speculum-treatment. Dr. Addison, whom our good monitor quotes with just approval, confined his local measures to cold astringent washes, and seems to have found them sufficient. I doubt exceedingly whether he ordinarily made any digital examination. In a majority of hysterical cases we may, I fully believe, follow his example; and in the remainder, either alone or with Dr. Tilt's aid, we can search for flexures, malpositions, endometritis, subacute ovaritis, and all the possible excitants of hysterical disorder. Yet it may be as well to remember that Robert Ferguson (see prefatory essay to Gooch's Works) gives most unfavourable testimony as to the effects of local treatment in a very kindred condition. The sufferers "go from specialist to specialist, and generally, after years of trial and endless expense, subside into invalid habits unrelieved." I am, etc.,  
December 1871

C. HANDFIELD JONES.

### THE COMING RACE.

SIR,—I had expected that Mr. Berkeley Hill's letter, and your editorial comments in the JOURNAL of the 25th ult., would have provoked a reply from some of the London teachers; but, as none has appeared, will you allow me space for a few remarks?

I have not attended any of the examinations at the College of Surgeons, so that I cannot speak of them from personal observation; but I am satisfied that they are quite up to the attainments of those examined, and that there is scant cause for complaint as to the treatment which the candidates receive. Indeed, if I express my own feeling, it is that too much, rather too little, leniency is shown by the examiners; for I do not hesitate to say that I have never known students go up for their surgical examination so ill prepared and so unfitted for practice as at the present time. This is a lamentable statement to make; but I feel sure that most of my fellow-teachers at the London schools will confirm it.

To what, then, must we attribute this? Is it the fault of the students, of their examiners, or of their teachers? or must we seek the cause elsewhere?

1. I do not think that it is the fault of the students. At no time in my experience has the general body of students been so good, whether regarded from a social or an educational point of view, as now; and I do not consider them a whit more idle, or less in earnest, than formerly.

2. We are agreed that the examinations of the principal Examining Boards are not only fully up to, but well in advance of, the level of the candidates who present themselves; so the blame does not attach there.

3. You, sir, seem to think that it is the imperfect systematic teaching in our medical schools, and more particularly the clinical teaching, which is responsible for the shortcoming of the students; and Mr. Hill, by implication, does so too. But here I join issue with you; for, during the twenty years that I have been in London, there never was a time when clinical teaching, incomplete though it yet may be, was carried out nearly to the same extent as at present; nor when equal opportunities for learning his profession were offered to the student, by the varied appliances everywhere provided; by the activity of the demonstrators and other subaltern officers in the schools; by the appointment of a medical tutor almost everywhere, to assist the student in his studies, and prepare him for examination; and by the personal labour and attention bestowed by most hospital teachers upon any individual pupil who shows the slightest desire and aptitude for instruction. If there be a prominent fault just now in our manner of teaching, it seems to me that it lies rather in doing too much for the students, and that we are in danger of making education far too easy for them.

I do not think, then, that your panacea of publishing tables from the Colleges to show the numbers passed and rejected from each school would be of much service, though I am quite willing it should be tried. In my opinion, the teachers are doing their work fairly well; and we must look away from them for the real cause of failure. This, I believe, to be due to two things: 1, the very insufficient time now devoted to work in the hospital wards; and, 2, the pernicious practice which still obtains of employing mere lads as assistants who have had little or no preliminary study.

According to the present regulations, a student must be engaged for four years in the acquirement of professional knowledge, of which two and a half years must be passed at a recognised school and hospital; whilst the other eighteen months may be either spent in the same way, or with some legally qualified practitioner who holds a public appoint-

ment. The outcome of this is that the majority of our students pass only two and a half years at the hospitals, in which time they are expected to gain a sufficient amount of knowledge to fit them for the exigencies of practice. Of this very limited period, the first eighteen months are necessarily devoted almost exclusively to the acquirement of enough anatomy and physiology to pass an examination in these subjects; for, although the student may attend hospital practice and other lectures during his second winter sufficiently "to get signed", he really is too much impressed by the impending examination to pay attention to anything else. If successful in April or May, after a short holiday, which he has well earned and really needs, he returns to town and passes his second summer session in preparing for his primary examination at the College of Physicians or Society of Apothecaries, attending just enough lectures on midwifery and jurisprudence to obtain signatures to his schedule. A third winter session now remains—a period of six months—in which he has to acquire a sufficient knowledge of medicine, surgery, and midwifery, to undergo an examination in these subjects; and, if he pass this, he obtains a diploma and becomes legally qualified to gain practical experience at the expense of the public. So strongly is this responsibility felt by many of our best students, that, if they cannot get a public appointment, they take an assistantcy for a time to educate themselves in the practical part of their profession; whilst those who are less alive to their real position, or from circumstances are compelled to do so, boldly commence practice on their own account with the very limited knowledge at their disposal.

I have not drawn an exaggerated picture, but have simply given the hospital career of students who work hard and strive to command success; and can we then be surprised that, with only six months, or nine at the very utmost, in which to learn the science and art of medicine, surgery, and midwifery, they should go up for examination ill-prepared to pass, or that a deplorable want of practical knowledge should be exhibited by even the most intelligent and industrious of them? It is the system, then, that I consider responsible for the present unsatisfactory state of things, and not the students, the teachers, or the examiners as such, but only so far as they may be councillors of the several colleges and still permit such a reprehensible system to continue.

The remedy which I would suggest, with all deference, is, that at least five years of study be required of every man before he be allowed to become a registered practitioner, of which four full years should be passed at a recognised school and hospital. The first two of these should be devoted exclusively to the scientific subjects, especially anatomy and physiology; and an examination in these should be required before he is allowed to commence the other part of his curriculum. This test over, the last two years should be given up to the acquirement of the more purely professional subjects, such as medicine, surgery, midwifery, jurisprudence, toxicology, etc. Having passed an examination in these, he should receive, not a diploma, but a *licence to practise as an assistant*, and should be required to act either as house-surgeon to a hospital or some public institution, where he would be under the supervision of a qualified man, or else to become assistant to a general practitioner for twelve months; at the end of which time he should be submitted to a final examination in practical subjects, and then, if successful, he entitled to a diploma and to be placed upon the Register.

By this means, we should gain that *sine qua non*—an additional year of hospital study—and the student could direct his undivided attention to the subjects required of him in each period of two years spent there. The time now worse than wasted in a surgery before joining a medical school, would be profitably employed in practice under the surveillance of a responsible man after a full course of medical education; and the examinations could then be made more searching and more practical, whilst they would be really less difficult for the student.

The increased expense of education will, no doubt, be urged *inter alia* as an objection to this suggestion; but I say at once that I regard that as a point in its favour: the facilities for entering the medical profession are now too great, and the pecuniary one is not the least of them. Moreover, we should by this plan abolish altogether apprentices and unqualified assistants—i.e., the objectionable practice of employing cheap unskilled labour to the detriment of the skilled educated man; and the demand, consequently, for assistants would be sufficient to enable those licensed, as I propose, to earn at least a livelihood during their last twelve months of practical study.

Many other advantages could be urged, but I have already exceeded all reasonable limits; and, with apologies for such a long communication, I am, etc.,  
GEO. G. GASCOYEN.

London, December 16th, 1871.

\* \* \* We have reason to believe that the letter addressed to us on this subject, purporting to be from a student of Guy's Hospital, was a forgery. Inquiries are on foot to detect its author.

# THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

## POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

126, Gower Street, Dec. 13th, 1871.

SIR,—I shall feel obliged if you will insert the enclosed letter, which I have just received, in the *BRITISH MEDICAL JOURNAL*.

I am, etc., J. WICKHAM BARNES, Hon. Sec.

“Worcester, Dec. 12th, 1871.

“Dear Sir,—I enclose an extra subscription of five shillings, payable to Christmas 1871. I wish that every member would do the same, now that money is wanted for Mr. Corrance's Bill for next session, and an alteration is being made in the time at which subscriptions will become due. Under any circumstances, some odd shillings will have to be paid up to Christmas, and it would be but a graceful act on our part to at once forward five shillings each to enable those who are labouring in our cause and that of the sick poor to continue services which have truly been beyond all praise.—I am, dear sir, your faithfully,

“WILLIAM WOODWARD, M.D.

“To the Secretary of the Poor-law Medical Officers' Association.”

## POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND.

### *Address to the Poor-law Medical Officers.*

THE Council beg to remind the members of the Association and all Poor-law medical officers that Mr. Corrance, M.P. for East Suffolk, will, in the early part of the ensuing session of Parliament, introduce a bill having for its object a very considerable reform in the administration of Poor-law medical relief, and one largely affecting the status of Poor-law medical officers.

It is most desirable that the hands of Mr. Corrance should be strengthened to the utmost, and that the whole of the Poor-law medical officers in England should join the Association and unite in bringing their influence to bear on this great question of Poor-law medical reform. The Council earnestly impress upon the country members the importance of placing themselves in communication with their respective Parliamentary representatives, in order that they may bring under their immediate notice the objects of the Association, and obtain their sympathy and support in the House of Commons on Mr. Corrance's Bill.

A considerable number of the Poor-law medical officers already belong to the British Medical Association; and it is suggested that the interests of the Poor-law medical service might be further advanced by all Poor-law medical officers joining the British Medical Association, and enlisting its powerful, social, political, and professional influence, so that questions of Poor-law administration may be brought before the several Branches for discussion at their numerous meetings.

The Council have, in conjunction with the Irish Poor-law Medical Officers' Association, received the warm support and influence of the *BRITISH MEDICAL JOURNAL*; and questions of the highest importance affecting the status and pay of Poor-law medical officers have been freely discussed in that widely-circulated periodical. Among the topics of interest have been the question of gratuities for vaccination and for extra services rendered during the epidemic of small-pox; the superannuation of Poor-law medical officers; the evident intention of the Legislature in reference to the right of claiming superannuation; the question of fees in cases of lunacy; the *modus operandi* to be adopted in order to secure payment for the same, also with reference to ordinary and difficult cases of midwifery, etc. It is important that the valuable facts and deductions contained in the reports of the Association should receive the widest publicity. This may be largely aided by having extracts inserted in the local journals, or by forwarding the reports when read to the editors of local journals, and calling their attention to passages of local importance.

The Council feel that the Poor-law medical officers are capable of rendering the highest service to the commonwealth. Their claims have hitherto been insufficiently recognised, but by pointed and well-directed efforts it is in their power to secure a high and proud position in the estimation of the public. The work of the Poor-law medical officers is honest and noble, in a word national; by curing sickness and preventing disease they secure the wealth and strength of the country. Disease and poverty are so intimately connected that few can now fail

to recognise their inter-relationship as cause and effect. Surely our legislators cannot much longer fail to give to the health officers of the nation that position and remuneration which the fruits of their labours so richly entitle them to receive.

The Council trust that medical officers will kindly forward to Mr. Benson Baker, Corresponding Secretary, 42, Grove Road, St. John's Wood, London, cuttings from local journals, reports of Boards of Guardians, personal grievances, changes in appointments, vacancies, superannuations, gratuities, increase of salaries, obituary notices of colleagues, and notices of any parochial questions bearing on the medical service. Members will see the importance of having the above information published weekly. The names and addresses of correspondents will in no instance be revealed unless distinct permission be given, or when applied for the grounds of refusal.

The Council remind members that their subscription of five shillings will, by an alteration in the laws of the Association, fall due in January, and should be forwarded to the Treasurer, C. M. Frost, Esq., 47, Ladbroke Square, London. Poor-law medical officers desirous of joining the Association should communicate with J. Wickham Barnes, Esq., Honorary Secretary, Gower Street, W.C.

# THE POOR-LAW MEDICAL SERVICE OF IRELAND.

## POOR-LAW MEDICAL OFFICERS' ASSOCIATION, IRELAND.

### *Address to the Dispensary Medical Officers.*

THIS association, though still in its infancy, has already made its mark. It has numerous members in every county in Ireland, not only medical men connected with the Poor-law, but also other members of the profession. To those who have not already joined its ranks, we shall briefly state the objects which it has in view. Its primary intention is to unite the officers connected with the Poor-law medical service, in the various unions, counties, and provinces throughout Ireland, into an association, for the purpose of advancing their interests and redressing their grievances. Individual exertion or complaint possesses but little weight; but the outspoken opinion, on any subject within their province, of a body of men including half of the medical profession of Ireland, could hardly be ignored by any authority. This is the principal object in the formation of this association; and it was to promote it that we freely placed our columns at its disposal. The interests of other members of the medical profession (as far as they go) being identical with those of the Poor-law medical officers, it is not to be wondered at that many of these gentlemen have also joined the Association. Another desideratum is to raise the status of the medical officers, and thus increase their influence and power for usefulness, and to provide a channel through which all defects in the Poor-law medical service may be brought to light and discussed with a view to their removal or amelioration. For instance, one object is to obtain the whole payment of the salaries of medical officers from the State, thus making them to a certain extent a branch of the Civil Service, whereby promotion, increase of salary according to length of service, and compulsory superannuation, would take place. This would take from £60,000 to £70,000 a year off the rates, and might with great propriety be brought before the notice of the ratepayers and Boards of Guardians, as well as Members of Parliament, by the union and county representatives. It must be borne in mind that sickness is not local, but national; and it is but just that the expenditure caused by it should be national also. The principle of promotion is deserving of consideration; and the imposition of gratuitous medical duties must be watched with great jealousy. The want of such an association as the present enabled the passing of the Dangerous Lunatics Bill, by which all dispensary medical officers are obliged (when called upon to do so) to certify for dangerous lunatics “without fee or reward.”

The important work that has been performed by the Irish Poor-law Medical Officers' Association during the past year has been duly chronicled in the pages of this *JOURNAL* from time to time, but we will give a brief *resumé* of what has been done. Early in the present year, one of the first steps towards the principle of promotion amongst Poor-law medical officers in Ireland took place when Dr. Burke, of the Islandeany Dispensary, was appointed Poor-law inspector in place of the late Dr. Hill. On this occasion, at a meeting of the Dublin Branch of this Association, a resolution was passed that the Poor-law

Commissioners should be respectfully asked to consider the claims of the service in filling this important vacancy, which accordingly was done, with the best results. Lord O'Hagan's Lunacy Regulation (Ireland) Bill, as introduced in the House of Lords, contained a clause which would have imposed a very serious obligation on medical men in general in that country. Not only should they examine and certify for lunatics, but they should also send in to a central office a very elaborate report on each case within one week, under a penalty of £10. Provision was made in the Bill for the payment of all other persons concerned, with the exception of the medical men. This having been brought by the Association under the notice of Sir Dominic Corrigan, M.P. for Dublin, and Mr. Mitchell Henry, M.P. for Galway, who fought the battle in the committee-room of the House of Commons; and owing to their strenuous exertions and perseverance the obnoxious clause was ultimately withdrawn. In this instance, good and prompt service was also rendered by the Council of the Poor-law Medical Officers' Association of England, who forwarded, through their Chairman, Dr. Joseph Rogers, a petition to Dr. Lyon Playfair, M.P., for presentation to the House of Commons to the same effect. Circulars were also addressed, by the Secretary, to every Irish Member of Parliament, begging of them to be present in the House and see that justice was done to the medical profession on the occasion of the introduction of the Bill.

Shortly before the close of the last session, Sir Dominic Corrigan, M.P., Mr. McClure, M.P., and the Hon. D. Plunkett, M.P., introduced a Bill to amend the law relating to dangerous lunatics and dangerous idiots, and to make more effectual provision for the superannuation of the officers of district lunatic asylums in Ireland. This Bill was read for the first time and ordered to be printed; but, it being late in the session, and many important measures standing before it, it could not obtain a second reading. It will be brought forward again at an early period in the coming session. Under the Dangerous Lunatics Act (30 and 31 Vic., cap. 118), the justices may call to their assistance any dispensary medical officer, who shall examine any person asserted to be a dangerous lunatic without fee or reward. Up to the present time this may have pressed lightly on most of the dispensary physicians, but it must be borne in mind that they are all liable to be called upon to act at any moment; and within the past year several instances have occurred in which actions were taken against medical men who certified in cases of dangerous lunatics, and in more than one heavy damages were given against them.

There are many other grievances affecting the Poor-law medical service in Ireland to which the attention of the Association has been directed, and to which it is intended to draw attention at an early period, and to endeavour to remedy, if possible. Most of them have already been touched upon in these pages in the admirable and exhaustive papers by Mr. Benson Baker on the Irish Dispensary System, which appeared in the JOURNAL of October 28th and November 11th. To remedy these evils, however, it is necessary that there should be unanimity in the ranks of the service, and that every medical officer should assist in every way in his power to obtain those ends which we have already pointed out as the legitimate objects of the Association. We regret to find, however, that more than half of the Poor-law medical officers have not as yet joined the Association. It is true that in the weary hard-working life of dispensary practice many of them have little time for attending to other than their daily avocations; but it would give encouragement, afford aid, and set a good example, were they to enrol their names in the ranks of the Association, even should they do nothing else. When the time for action comes they can readily be advised as to what course to pursue. The events of the last few weeks leave but little doubt that in the coming session some comprehensive measure will be introduced, which will be likely to effect a complete regeneration and consolidation of our sanitary laws. This may be extended to Ireland, and may affect the Poor-law medical officers. We would counsel them to remember that there is a precedent in the Dangerous Lunatics Act that they should work "without fee or reward". The working members of the Association have already the subject under consideration; but they are few compared with the one thousand medical men scattered throughout Ireland, all of whom are, or ought to be, interested in the matter. The medical officers of each county ought to be in a position to address their parliamentary representative on the subject when the time arrives. In the meantime they should unite, look after their own interests, and enrol themselves in their own Association. The annual subscription (five shillings) is a trifling sum, yet it will be sufficient to cover the expenditure; and the advantages to be derived from united action can hardly be over-estimated. The Irish Poor-law medical officers may rely on the assistance of their English brethren and the hearty co-operation of the British Medical Association.

Members of the Irish Poor-law Medical Officers' Association will please bear in mind that the subscription for the year 1872 will become due on the 1st of January, and is payable to A. O. Speedy, M.D., General Treasurer, 28, North Frederick Street, Dublin.

### THE "GUINEA FEE" IN IRELAND.

THE following letter refers to a subject of great importance to the members of our Association and of the profession generally in Ireland. Without identifying ourselves with the views expressed, we may invite for them the careful consideration and courteous discussion which the experience of our correspondent demands, and which the interest of the subject will probably suffice to secure.

SIR,—Being one of the oldest members of your Association, perhaps you would kindly afford me space to say a few words on the subject of "the guinea fee" in Ireland; and having long since retired from practice, I hope to be able to approach this matter in an impartial manner. I read in the JOURNAL of the 11th November last, that there are two causes which operate in producing the indiscriminate issue of dispensary tickets. The first is the difficulty of defining the term "poor person"; and the second is, that a guinea is asserted to be the doctor's fee in Ireland. Both these statements I believe to be strictly accurate. With regard to "the guinea fee", I have been long puzzled to understand how this absurdity ever obtained, and why it still does obtain, in Ireland. We all know perfectly well that the opinion of the most eminent physician or surgeon in Dublin, Belfast, Cork, or elsewhere throughout the country, can be obtained for a guinea. There are grades amongst Irish physicians and surgeons, of course, as to age, experience, superior attainments, special knowledge, and so forth. It is absurd, then, to imagine that the opinions of all are of equal value; yet we are told that the fee for all is the same. It will be said that the heads of the profession will only give one opinion for the "guinea"; whereas the less eminent will give four or five. This is beginning at the wrong end. The patient may require but one interview with the doctor. If he goes to the younger man, he considers that he throws away the difference. So, probably, he does not go to any medical man until his symptoms become aggravated, or a trivial disease has become a serious malady. If he do go, he makes up his mind to get full value for his money at once, and applies to the most eminent man in the neighbourhood, although he would have been perfectly satisfied with the junior man had he known that he would have taken a reasonable fee, say five shillings. This is simply ruinous to the hopes of practice of the younger members of the profession; nor is it an unqualified advantage to those at the top of the wheel, because, as things exist at present, it is not an uncommon occurrence for a sick person to go to the nearest apothecary, and get one of the assistants to prescribe some *placebo* "for the more trivial complaints", whereas the patient would gladly seek the advice of a qualified man if he was sure that his fee was not beyond his moderate means, and knew where to find it.

With all due respect to my old *confrères*, I assert that, with the exception of the well known heads of the profession, and some of the hospital physicians and surgeons, a guinea or a pound is not the fee, at least not the fee per visit, that they do receive in Ireland, and that five shillings is much nearer the actual amount. The assertion that the former is the fee is clearly injurious to the practice of the younger members of the profession; and, what is still worse, it is injurious to the health of the public; because, as demand will always create supply, a class of practitioners is springing up in every city in Ireland, many of whom, I grant you, are well qualified men, but a vast number, I fear, owe their non-appearance in the *Medical Directory* not exactly to extreme modesty. These practitioners make no secret that their fee is five shillings. As a rule, they have very fair practice, while well qualified and able young men have none, because, forsooth, they permit their would-be patients to labour under the delusion that they will not accept less than "the guinea fee." In fact, at present, the patient does not, as a rule, know what fee to offer; and the doctor, if asked, feels very uncomfortable; says, "My fee is a guinea, of course", and takes five shillings. I have often heard the following argument made use of: "demand a guinea from those able to pay that sum, and tone down your fee to suit the circumstances of the patient." This appears to me to be about as honest as that a merchant should charge a rich man more than a poor man for the same article.

Another important point to be considered is this: the demoralising effect that the hypothetical "guinea fee" has upon certain classes of the community. The facility for obtaining medical relief under the Poor-

law is very great, perhaps too great, in Ireland. Many persons avail themselves of this because they either believe, or say they believe, that a guinea is really the fee; and it always affords a plausible argument to be turned when necessary against the dispensary doctor who complains of the indiscriminate issue of tickets. Some years ago, a dispensary became vacant in this union; and we endeavoured to obtain a physician who would agree to take five-shilling fees; several of the candidates declared that it would be *infra dig.* to do so. I remarked that these were fresh from the schools, young men in the pride of their youth. The gentleman who holds the appointment now on this understanding, finds it to be very much to his advantage; and the more liberal members of the committee are now able to place some restriction on the indiscriminate issue of tickets, which they could not have attempted to do if the allegation could be brought forward that the doctor's fee was "a guinea." If every dispensary doctor in Ireland would make it known to his committee that he would take a fee of 5s., or in certain cases even 2s. 6d., it would, I have no doubt, very much curtail the issue of dispensary tickets, and I think that it would meet with the approval of the Commissioners also. Having a very fair knowledge of the working of country dispensaries, I am aware that in many districts it is not a thing unknown that the doctor should receive his fee in kind, the patient not liking to be attended for nothing, and not wishing to insult him by offering him less than a guinea.

I have for a long time thought of writing to you, sir, on this subject, in the hope that perhaps you might, if space permitted, publish these few words of advice to the younger members of the profession. I have heard that a feeling in this direction is springing up amongst them; but they do not as yet appear to have the hardihood to take any decided step in the matter. At present, it comes very much to this: in cities, the belief that the fee is a guinea keeps many patients from the young practitioner's study; if he insist on the guinea, he has none. In country districts, because of the hypothetical guinea, he must attend gratuitously, and under much greater responsibility, on the dispensary ticket.

Why not take at once the better and bolder course? adopt the fee they actually do receive, and cease to take any part in the farce of "the guinea fee."

I am, etc., AN "EX-OFFICIO" GUARDIAN.

## MEDICAL NEWS.

### THE PROVIDENT SYSTEM OF MEDICAL RELIEF.

The paper on the Medical Aspects of Pauperism, read by Mr. Fairlie Clarke at a meeting of the Metropolitan Counties Branch of the British Medical Association in March last, resulted in the formation of a Committee of the Society for the organisation of charity, to inquire into the working of the present system of gratuitous hospital relief, and to advise upon the best means of remedying those abuses of it which are believed to be injurious to the public and unjust to the medical profession. The Committee has prepared a series of rules which are suggested for the management of Provident Dispensaries. A large and important conference, presided over by Mr. W. H. Smith, M.P., and attended by Mr. Stansfeld, President of the Local Government Board, and by sundry influential physicians and others, was lately held under the auspices of the Society. The subjects discussed at the conference were, the excess in the numbers of those who seek gratuitous attendance in the out-door departments of our medical charities, and the best means of providing medical assistance for the industrious poor, at a rate within their means, and which shall avoid pauperising them. The meeting adopted resolutions which condemned the present indiscriminate relief, and recommended the more general adoption of medical assurance, of which the object should be to provide and pay for medical assistance during illness to the industrial classes, without resort to charity.

In order to afford further opportunities of eliciting the matured opinion of the medical profession on a subject which affects to a great extent the interests of large classes of the community, it is proposed to hold a meeting of the Metropolitan Counties Branch at the commencement of the parliamentary session, with the object of discussing once more the subject of the provident system of medical relief from a national as well as from a professional point of view. This meeting, if it be held, will be one of great importance to the profession and the public; and we understand that it is intended to invite the attendance of a number of influential members of Parliament, who have by their hospital connections and otherwise acquired a knowledge of this subject or proved their interest in it. Due notice of the meeting will be given. In the meantime, we commend the subject to the especial

attention and thought of the many thousand members of our Association and of the profession at large. It is desired to elicit not only the opinions and experience favourable to such changes as have been proposed, but all carefully formed opinions which bear upon the subject from every point of view. It may be useful in anticipation of the meeting, for those who have accumulated experience in any parts of the subject to communicate it by letter; and we shall willingly open our columns to such communications. They may bear either upon the working of the present system in hospitals, dispensaries, provident dispensaries, and sick-clubs, or upon any suggested methods of treating the difficulty which may vary from the proposed code of rules of the Committee of the Organisation Society, which we published in the JOURNAL of October 28th. Copies of these rules, which have been revised and separately printed, may be obtained from Mr. Lewis, publisher, Gower Street.

### SMITH'S MEDICAL DIARIES.

THESE excellent diaries and visiting lists, which have for many years received constantly increasing professional favour, are this year still further improved by the addition of posological and other lists from the last edition of Squire's *Companion to the Pharmacopoeia*, and by the incorporation of the new postal regulations. They are exceedingly convenient and well arranged.

### THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

The following list of the bulletins issued is continued from the list which we published last week.

Dec. 14, 10 P.M.—His Royal Highness the Prince of Wales has passed a quiet evening, and continues in the same state.

Dec. 15, 1 A.M.—His Royal Highness the Prince of Wales is passing the night very quietly.

Dec. 15, 8 A.M.—His Royal Highness the Prince of Wales has passed a quiet night. The debility is great, but the general conditions are more favourable.

Dec. 15, Noon.—His Royal Highness the Prince of Wales has passed a tranquil morning. The symptoms are still favourable.

Dec. 15, 5 P.M.—His Royal Highness the Prince of Wales has passed a tranquil afternoon. The course of the symptoms continues favourable.

Dec. 15, 10 P.M.—His Royal Highness the Prince of Wales has passed a quiet evening. The conditions remain the same.

Dec. 16, 1 A.M.—His Royal Highness the Prince of Wales has had some quiet sleep.

Dec. 16, 8 A.M.—His Royal Highness the Prince of Wales has passed a tranquil night. The favourable course of the symptoms continues.

Dec. 16, 5 P.M.—His Royal Highness the Prince of Wales has passed a very tranquil day. The progress is in all particulars satisfactory.

Dec. 17, 9 A.M.—His Royal Highness the Prince of Wales has passed a quiet night, and continues to make satisfactory progress.

Dec. 17, 5 P.M.—His Royal Highness the Prince of Wales has passed the day tranquilly. No change since morning.

The reports of the physicians from this date indicate steady and satisfactory progress.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College, on Monday, December 18th, the following was admitted a Fellow.

Bishop, Thomas, M.D. Aberd., Rue de Matignon, Faubourg St. Honoré, Paris. The following passed his primary professional examination.

Murphy, John Francis, Queen's College, Cork. The following gentlemen, having conformed to the bye-laws and regulations, and passed the required examination, were granted Licences to practise physic, including therein the practice of medicine, surgery, and midwifery.

Bailey, Francis James, M.R.C.S., Grove Street, Liverpool  
 Bramant, Thomas Hughes, M.R.C.S., North Audley Street  
 Carr, William Ward, M.B. Lond., Lee Grove, Blackheath  
 Comber, Frank, M.R.C.S., Trinity Square, London  
 Davies, Arthur Evelyn, M.R.C.S., Penner House, Newport, Monmouthshire  
 Eardley Wilmot, Robert, M.R.C.S., King's College Hospital  
 Franklin, George Cooper, M.R.C.S., Victoria Park Hospital  
 Fraser, John, M.D. Toronto, Strabane, Ontario, Canada  
 Graham, James Elliot, M.D., Toronto, Canada  
 Hemming, John Lamond, M.R.C.S., Southwick Place, Hyde Park  
 Jalland, William Hamerton, M.R.C.S., Guy's Hospital  
 Langridge, George Thomas, M.R.C.S., Myddelton Square  
 Lees, Frederic Arnold, M.R.C.S., Meanwood, near Leeds

Parker, Walter Augustus, M.R.C.S., Cathcart Road, Brompton  
 Rees, Howell, M.R.C.S., Yatalyfera, Swansea  
 Rowland, Edward Roger, M.R.C.S., St. George's Place  
 Ryley, Henry, L.R.C.P. Edin., Fulbourn, Cambridge  
 Sergeant, Edward, M.R.C.S., St. Thomas's Hospital  
 Todd, William James, M.R.C.S., Gloucester Road, Regent's Park  
 Younger, Edward George, M.R.C.S., Holly Mount, Blackheath Hill  
 Duke, Douglas William, who passed his examination in medicine, July 1871, and has obtained a recognised qualification in surgery.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 14th, 1871.

Bosworth, John Routledge, Sutton, Surrey  
 Grayson Francis Dorrell, Henley-on-Thames  
 Harris, John Delpratt, Exeter  
 Hopkins, Frederick Fraser, Henley-in-Arden  
 Millner, Edward, Birmingham  
 Moseley, William Arthur, Nassau, Bahamas  
 Pitt, Isaac, Birmingham

The following gentlemen also on the same day passed their first professional examination.

Cave, Alfred Ernest, London Hospital  
 Eady, George John, King's College  
 Gard, William John, Guy's Hospital  
 Griffith, Alfred Vavassour, Queen's College, Birmingham  
 Joynes, Francis James, King's College  
 Parkes, William Edmund, Queen's College, Birmingham  
 Vincent, Henry Bird, St. Bartholomew's Hospital

As an Assistant in compounding and dispensing medicine.

Jones, Morgan, Chipping Sodbury

### MEDICAL VACANCIES.

**THE following vacancies are announced:—**

BALFOUR HOSPITAL, Kirkwall—Medical Officer.  
 BALLINROBE UNION, co. Mayo—Medical Officer for the Ballinrobe Dispensary District: £100 per annum.  
 BATTERSEA, Parish of—Medical Officer of Health for the Eastern District: £50 per annum.  
 BRIGHTON and HOVE DISPENSARY—Two Surgeons.  
 BRIGHTON and SUSSEX EYE INFIRMARY—Consulting Surgeon.  
 CARMICHAEL SCHOOL OF ANATOMY, MEDICINE, and SURGERY, Dublin—Lecturer on Anatomy.  
 CARNARVONSHIRE and ANGLESEY INFIRMARY and DISPENSARY, Bangor—House-Surgeon: £80 per annum, board and lodging.  
 CORK UNION—Medical Officer for the Blackrock Subdistrict of the Cork Dispensary District: £100 per annum.  
 DORSET COUNTY HOSPITAL, Dorchester—Physician.  
 EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN—Physician.  
 EAST SUSSEX, HASTINGS, and ST. LEONARD'S INFIRMARY—Physician; Assistant-Physician.  
 GOREY UNION, co. Wexford—Medical Officer and Public Vaccinator for the Kellena and Wells Dispensary District: £100 per annum, and fees.  
 JERSEY GENERAL DISPENSARY—Resident Visiting and Dispensing Medical Officer: £100 per annum, furnished rooms, attendance, coal, and gas.  
 KEIGHLEY UNION, Yorkshire—Medical Officer for the Bingley District: £50 per annum.  
 KILBURN, MAIDA VALE, and ST. JOHN'S WOOD GENERAL DISPENSARY—Resident Medical Officer: £100 per annum, furnished rooms, £45 per annum for a dispenser and servant, coal and gas.  
 KILRUSH UNION, co. Clare—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Cragknock Dispensary District: £100 per ann., and fees.  
 KING'S COLLEGE, London—Professor of Forensic Medicine.  
 LANCASHIRE LUNATIC ASYLUM, Prestwich—Medical Superintendent: £600 per annum, house (partially furnished, and free of rates and taxes), coal, gas, and washing.  
 LISMORE UNION, co. Waterford—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Lismore Dispensary District: £100 per annum, and fees.  
 LIVERPOOL DISPENSARIES—Assistant Resident House-Surgeon: £108 per annum, furnished apartments, coal, gas, and attendance.

 NUNEATON UNION—Medical Officer and Public Vaccinator for the Nuneaton District: £55 per annum, and extra fees.  
 OXFORD—Medical Officer of Health.  
 RIPON UNION, Yorkshire—Medical Officer for District No. 3: £30 per annum.  
 SOUTH STAFFORDSHIRE and WOLVERHAMPTON HOSPITAL—Secretary: £100 per annum, board and residence.  
 STOCKWELL FEVER HOSPITAL—Resident Medical Superintendent: £400 per annum, unfurnished residence, coal, and gas.  
 SUDBURY UNION, Suffolk—Medical Officer for the First District: £55 per annum, and extra fees.  
 SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds—Physician.

SUNDERLAND INFIRMARY—Junior House-Surgeon: £80 per annum, board, lodging, and washing.  
 THOMASTOWN UNION, co. Kilkenny—Medical Officer, Public Vaccinator, and Registrar of Births, etc.: £95 per annum, and fees.  
 TROON—Medical Inspector of Seamen.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

\*BANKART, James, M.B., appointed Surgeon to the Devon and Exeter Hospital, vice \*P. C. Delagarde, Esq., deceased.  
 \*BEACH, Fletcher, Esq., appointed House-Surgeon to the Children's Hospital, Great Ormond Street, vice W. O. Sankey, Esq., resigned.  
 BRUCE, John, M.B., appointed Medical Officer and Public Vaccinator for the Parishes of Birkwall and St. Ola, Orkney.  
 \*COLES, George Charles, Esq., elected Assistant-Surgeon to the Central London Ophthalmic Hospital.  
 LOWE, John, M.B. and C.M., appointed Assistant Medical Officer to the Durham County Asylum, Sedgfield, Ferryhill.  
 SAUNDERSON, Dr. Charles, elected Medical Officer, etc., for the Kiltormer Dispensary District of the Ballinasloe Union, co. Galway.  
 THOM, Alexander, L.R.C.P. Edin., appointed Medical Officer for the Parish of Crieff, Perthshire.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

#### BIRTHS.

BEADLES.—On December 20th, the wife of \*Arthur Beadles, Esq., Surgeon, Forest Hill, of a son.  
 CHAMBERS.—On December 6th, at Sutherland Street, the wife of \*Thomas Chambers, M.R.C.P.  
 CLOUSTON.—At Garlands, Carlisle, on December 13th, the wife of \*Thomas S. Clouston, M.D., of a daughter.

#### MARRIAGE.

MITCHELL, Harrison, M.D., of Wigton, to Alice, eldest daughter of Joseph FLEMING, Esq., of Cockermonth, on December 14th.

#### DEATHS.

\*COWDELL, Charles, M.D., Physician to the Dorset County Hospital, at Dorchester, aged 56, on December 15th.  
 \*HUGHES, William Lewis, Esq., Surgeon, of Llanrhaidr-yn-Mochnant, at Liverpool, aged 29, on December 10th.  
 RAINES, Charles, Esq., Surgeon, at Hull, aged 22, lately.  
 SINGLETON, William, M.D., late Surgeon of Her Majesty's 47th Regiment, at Cap-paduff, co. Mayo, on December 5th.  
 SYKES, Reuben, Esq., Surgeon, at Doncaster, aged 46, on December 9th.  
 TINNIION, John, M.D., at Templehill, Troon, N.B., aged 56, on December 11th.

**ROYAL COLLEGE OF SURGEONS.**—At the preliminary examinations for the diplomas of fellowship and membership of the Royal College of Surgeons, which was commenced on Tuesday last and only brought to a close yesterday. Two hundred and eighty-eight candidates presented themselves, viz: 68 for the first-named distinction, and 220 for the latter. The result of the examination, which is conducted by a staff from the College of Preceptors, under the superintendence of Dr. Jacob, cannot be known until early in the ensuing year.

The next Actonian Prize or prizes offered by the Royal Institution, will be awarded in the year 1872 to an essay or essays illustrative of the wisdom and beneficence of the Almighty. The subject is "The Theory of the Evolution of Living Things." The prize fund is two hundred guineas, and it will be awarded as a single prize, or in sums of not less than one hundred guineas each, or withheld altogether, as the managers in their judgment shall think proper. Competitors for the prize are requested to send their essays to the Royal Institution, Albemarle Street, on or before June 30th, 1872, addressed to the Secretary, and the adjudication will be made by the managers in December 1872.

**BEQUESTS, DONATIONS, ETC.**—The General Hospital, Birmingham, has received £500 under the will of Mrs. Sutton, and become entitled to £100 under the will of Mr. Thomas Munden.—The South Staffordshire General Hospital, Wolverhampton, has received £450 from Mrs. Cobbe, of Leamington, in accordance with the wish of her late sister, Miss Mary Ann Mitton; £100 under the will of Mr. H. B. Whitehouse; and £100 (towards the enlargement fund) from Mr. John W. Sparrow.—The Forfar Infirmary has received £200 under the will of Mr. William Roberts, Town Clerk of Forfar.—The Brechin Infirmary has received £100 under the will of Mr. James Carnegie Arbuthnot, of Balmahoon.—Miss Wood, of Upper Hermitage, Edinburgh, has bequeathed £2000 to the Edinburgh Royal Infirmary.—The Whitehaven and West Cumberland Infirmary has received a legacy of £50 under the will of Mrs. Eleanor Dixon, and £75 subscribed by her relatives, both which amounts are to be invested, and to form an "Eleanor Dixon Memorial Fund", and the interest to be applied in providing clothing and bedding, when necessary, for convalescent patients on leaving the Infirmary.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

FOR replies to questions concerning Poor-law medical questions, see Poor law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Maunsell, Dublin.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

W. S. (Great Grimsby).—Dr. C. B. Radcliffe, Dr. Russell Reynolds, Dr. Ramskill, and Dr. Hughlings Jackson, have written ably upon these subjects.

WE have in hand, for early publication, lectures by Dr. Brunton on the Physiological Action of Medicines, Clinical Lectures by Dr. Barnes, Mr. Prescott Hewett, Dr. A. T. Waters, Mr. Campbell De Morgan, Dr. Priestley, Mr. Jonathan Hutchinson, Dr. Fuller, etc.; and papers by Dr. Swayne, Mr. Samuel Wood, Mr. Francis Mason, Dr. Shapter, Dr. L. Athill, Dr. C. Gibb, Dr. Marcet (Nice), etc.

EARLY in the year will be commenced courses of lectures by Dr. Murchison, Dr. Braxton Hicks, F.R.S., and Dr. Morell Mackenzie. The important letters of Dr. Rumsey and of Dr. C. J. B. Williams, F.R.S., will be published next week.

A CONSTANT READER (Bristol).—Dr. Ferrier will next week answer the question as to Pasteur's solution in the zymotic test.

DR. A. W. EDIS (London).—The advertisement was received under misapprehension, and will not be continued after expiration of contract. We are glad to have had our attention called to the facts.

## THE LATE ACTION AGAINST A MEDICAL MAN.

SIR,—Will you allow me through your columns to acknowledge the following subscriptions on behalf of the Testimonial Fund now being raised for Dr. D. H. Watson, of Stockton, whom it will be remembered was honourably acquitted of a charge of unskilful treatment, recently brought against him by a Miss Hutchinson, in the management of a difficult case of inverted uterus. Although getting a verdict and an order for costs against the plaintiff, Dr. Watson is still called upon to discharge a very heavy amount incurred during the conduct of his case, and which, from the inability of the plaintiff to meet the costs which have been incurred, he will have to pay. I have received the following sums:—

£ s. d.			£ s. d.				
Dr. Warburton Begbie, Edin.	2	2	0	E. H. Hughes, Esq., Stockton	1	1	0
Dr. Wm. Oliver, Stockton	1	1	0	A. Stocks, Esq., Stockton	1	1	0
Dr. George Oliver, Redcar	1	1	0	Dr. Timmswood, Norton	1	1	0
Dr. B. Meadows, London	1	1	0	A Friend (R. L.), Stockton	1	1	0
A. Davidson, Esq., Crum- lington	1	1	0	E. Mandall, Esq., Stockton	1	1	0
S. W. Kayne, Esq., New- castle	1	1	0	Dr. Cathbertson, Strling, N.B.	0	10	6
Dr. G. H. Hume, Newcastle	1	1	0	Pybus, Esq., Stockton	0	10	0
C. G. Wood, Esq., Pease, Sunderly	1	1	0	W. J. Watson, Esq., Stockton	0	10	0
J. Barnard, Esq., Stockton	1	1	0	Mr. Hudson, Stockton	0	10	6
				Anon., Stockton	0	10	6
				Mr. S. Bowen, Stockton	0	10	0
				Mr. J. Walton, Stockton	0	5	0

Further subscriptions will be thankfully received by Dr. W. Oliver, Stockton-on-Tees; Dr. G. H. Home, Westgate Street, Newcastle; or by Yours faithfully, GEORGE S. BASHAM, Hon. Sec. Stockton-on-Tees, December 18th, 1871.

C. J. (Barnstable), and D. M. (of the same place).—The result of the examination in Arts at the College of Surgeons cannot be known until about the middle of January, owing to the large number of papers to be read from upwards of three hundred candidates.

MR. M. (Exeter).—It is a common superstition in Devonshire and Cornwall to impute of any one calling on a pyrothol house of a remedy for the hooping cough; and whatever may be named is regarded as an infallible specific.

MR. WILLIAMS, General Secretary, respectfully requests the honorary Branch Secretaries to forward to him, as soon as possible after the 31st instant, all subscriptions received by them up to that date, being subscriptions for 1871 in arrears for previous years. The Secretary again appeals to members who have not yet paid for 1871 to do so without delay.

DOUBLE MONSTERS.—Teratologus will find a very interesting lecture on the Ohio Twins, by Dr. Goodell, in the *Philadelphia Medical Times* of June 15th, 1871; and large bibliographical and critical references in papers on Diploaterology, by Dr. J. G. Fisher, in the *Transactions* of the Society of the State of New York, 1865, 1866, 1867, and 1868; and a letter by the same author, in the *Philadelphia Medical Times* of July 15th, 1871.

INGENUOUS CACOGRAPHY.—Druggists need to be skilful in deciphering hieroglyphics under the most unfavourable circumstances. The following specimens of orthographical ingenuity were recently successfully deciphered. In one case, an order for "3 Peneth of Crotch Needle from chemest", on inquiry, proved to be cochineal; and in another, on a small slip of paper, which was accompanied with a bottle and twopence, were inscribed the words: "Ek peke quike anna wine."—In a list of articles ordered from a country druggist which we have seen, the following occur: "saver latin"; "1 ouns of Kye an peper"; "2 ouns of white murkeram"; "4 ouns of perm an isity"; "2 pounds of venes turtine".

## PRIZE ESSAYS.

SIR,—Would you be so good as to say (1) what, if any, prizes are open to the profession at present, irrespective of subjects; (2) with whom essays are to be lodged; (3) if previous publication of an essay in whole or in part debars it from being entered in competition. I am, etc., ALIQUIS.

PSYCHOLOGIST (Manchester).—Sir Walter Scott notices a practice in Perthshire, where several wells and springs are dedicated to St. Fillan, and are places of pilgrimage and offerings even among the Protestants.

"Thence to St. Fillan's blessed well,  
Whose spring can frenzied dreams dispel,  
And the crazed brain restore."—*Marmion*.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The North Devon Herald, Dec. 14th; The Liverpool Weekly Albion, Dec. 16th; The Leeds Mercury, Dec. 14th; The Liverpool Daily Post, Dec. 12th; The Birmingham Daily Post, Dec. 15th; The Northampton Herald, Dec. 16th; The Scarborough Gazette, Dec. 11th; The Shield, Dec. 16th; The North British Daily Mail, Dec. 20th; The Salopian, Dec. 16th; The Brighton Daily News, Dec. 18th; The Eastern Morning News and Hull Advertiser, Dec. 11th; The Glasgow Herald, Dec. 19th; The Tralee Chronicle; etc.

Domville, London; An Associate; Dr. J. G. Wilson, Glasgow; Dr. James Finlayson, Glasgow; Mr. De Berdt Hovell, London; Mr. J. Liddell, Newcastle-upon-Tyne; Mr. Jonathan Hutchinson, London; Mr. Gilder, Derby; Messrs. Blackwood, Edinburgh; The Secretary of the Royal Medical and Chirurgical Society; Dr. C. J. Gibb, Newcastle-upon-Tyne; Mr. E. C. Board, Clifton; Dr. H. Maudsley, London; Our Liverpool Correspondent; Dr. Dickinson, London; A. P.; Aliquis; The Secretary of the Harveian Society; Mr. Spencer Smith, London; Dr. F. T. Roberts, London; Dr. Langdon Down, London; Dr. Fitzgerald, London; Mr. A. E. Durham, London; Mr. James Hinton, London; Dr. Hawksley, London; Our Vienna Correspondent; Dr. Woodhouse, Reading; Mr. G. S. Banham, Stockton-on-Tees; Mr. H. Arnott, London; Dr. Morton, Glasgow; Dr. Kelburne King, Hull; Mr. G. Gascoven, London; Mr. W. Mac Cormac, London; Dr. McIntyre, Odiham; Mr. J. Marshall, London; Mr. F. C. Annesley, Jersey; Dr. B. W. Foster, Birmingham; Mr. George C. Coles, London; Mr. Frankland, Ripon; Dr. Percy Boulton, London; Mr. W. Allison, East Retford; Dr. Mark Long, London; Dr. Edis, London; Mr. P. H. Holland, London; Mr. J. C. O. Will, Aberdeen; Dr. C. Handfield Jones, London; Dr. C. F. Moore, Dublin; Dr. R. Liveing, London; Dr. Robertson, Glasgow; Dr. Paul, London; Dr. S. Felce, London; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Mr. Holthouse, London; The Secretary of the Royal College of Physicians; Mr. P. Grubb, Westminster; Mr. W. Gilder, Margate; Dr. Brunton, London; Dr. Ferrier, London; Dr. R. Barnes, London; Dr. Liebreich, London; Mr. Gant, London; Mr. E. Sandwell, London; Mr. Felton, London; The Secretary of the Fever Hospital, London; Mr. Thomas Cooke, London; Dr. Silver, London; Mr. Hulke, London; Mr. H. Morris, London; etc.

## BOOKS, ETC., RECEIVED.

The Medical Guide to Scarborough; giving an Account of its Climate and Vital Statistics; with Directions for Sea-bathing and Taking the Waters. By C. B. Brearey, M.D. Fourth Edition. Newcastle-upon-Tyne: 1871.

Memoranda on Poisons. By the late Thomas Hawkes Tanner, M.D., F.R.S. Third and completely revised Edition. London: 1872.

A Manual of Zoology for the Use of Students; with a General Introduction on the Principles of Zoology. By Henry Alleyne Nicholson, M.D., M.A. Second Edition, revised and enlarged. Edinburgh and London: 1871.

Transactions of the Odontological Society of Great Britain. Vol. iv, No. I. New Series. London: 1871.

## LECTURES

ON THE

## EXPERIMENTAL INVESTIGATION OF THE ACTION OF MEDICINES.

By T. LAUDER BRUNTON, M.D., D.Sc.,

Joint Lecturer on Materia Medica, and Casualty Physician, at St. Bartholomew's Hospital; etc.

## IV.—DETERMINATION OF THE EXACT STRUCTURES THROUGH WHICH DRUGS AFFECT THE HEART AND VESSELS.

*Comparison of the Effects of Drugs on different Animals in different Doses.—Mode of determining the Exact Cause of Symptoms.—Mode of raising Blood-pressure.—Modes of counting the Beats of the Heart.—Causes of Quickened Pulse.—Direct Stimulation of the Sympathetic.—Stimulation of Cardiac Ganglia.—Paralysis of the Vagus-roots and Fibres, and of its ends in the Heart.—Causes of Slow Pulse.—Irritation of Vagus-roots.—Mode of supplying the Head and Body with different kinds of Blood.—Indirect Irritation of Vagus-roots through the Blood-pressure: mode of lowering and raising it.—Reflex Irritation of Vagus-roots.—Indirect Irritation through the Respiration.—Irritation of Vagus-fibres.—Increased Conducting Power of Fibres.—Stimulation of Vagus-ends.—Paralysis of the Sympathetic.—Paralysis of the Cardiac Ganglia.—Part of the Ganglionic Apparatus Affected.—Nervous System in the Heart.—Motor Ganglia.—Stimulating Ganglia.—Inhibitory Ganglia.—Connecting Apparatus.—Action of Drugs on the Inhibitory Apparatus.—Nicotia, Muscaria.—Antagonism of Atropia and Physostigma: bearing of this on Therapeutics.—Paralysis of Co-ordinating Apparatus.—Paralysis of the Muscular Fibres of the Heart.—Blood-pressure: mode of determining whether changes in it are due to alterations in the Heart or Vessels.—Elimination of the Action of the Heart: Division of its Nerves.—Irritation of Vagus.—Ligature of Aorta.—Artificial Circulation; in Mammals, in the Frog.—Observation of Vessels.—Action on Vaso-motor Centre; on Vascular Walls.—Influence of the Action of Parts surrounding the Vessels upon them.—Action of the Pulmonary Circulation on the Blood-pressure.—Use of the Sphygmograph.*

**ACCELERATING GANGLIA IN THE HEART.**—We infer the presence of quickening ganglia in the heart, from the effects produced by irritating the vagus after its inhibitory power has been destroyed by the administration of nicotia or atropia. When irritation is then applied to the nerve, it no longer produces retardation, but, on the contrary, a decided acceleration of the cardiac pulsations. This shows that the vagus contains fibres which quicken the heart, and that these are unaffected by the drugs which have paralysed the others. The quickening, however, does not take place till some time after the application of the irritant; and, if it be applied only for a short time, no acceleration may take place till after its removal; but, after it does occur, it remains for a considerable time. If we irritate the heart directly, instead of irritating the nerve, its beats are quickened at once, and the acceleration does not last long after the irritation is discontinued. This shows that, when we stimulate the quickening nerves, we do not act directly on the motor ganglia *m* (Fig. 12), as we do when we irritate the heart itself, or as we should do if the quickening fibres ended directly in them; and we therefore infer the existence of the accelerating ganglia *q* between the quickening nerves *s* and the motor ganglia *m*. The accelerating apparatus seems to be stimulated by veratria; for we find that the cardiac pulsations are increased by its administration to mammals in which the spinal cord, vagi, sympathetics, and depressors, have all been divided, or when it is applied to the excised heart of a frog.

**IS QUICKENING OF THE EXCISED HEART DUE TO PARALYSIS OF INHIBITORY OR STIMULATION OF ACCELERATING GANGLIA?**—It is possible that the quickening may be due to paralysis of the inhibitory ganglia in the heart, and not to stimulation of the quickening ganglia. This can be decided by paralysing the inhibitory ganglia by means of atropia, before administering veratria. If the latter poison exercise a stimulating action on the quickening ganglia, it will quicken the heart after atropia has been applied. If it simply paralysed the inhibitory ganglia, it will have no further effect after the power has been destroyed by atropia. In the diagram, I have figured intermediate structures *c* and *d* between the quickening nerves and ganglia, so as to correspond with those of the inhibitory apparatus; but whether they really exist or not, we cannot at present say.

**IS THE CO-ORDINATING APPARATUS OF THE CARDIAC GANGLIA**

**PARALYSED?**—Regarding this apparatus we know almost nothing. When the heart is dying, its rhythm is often disturbed, and two or three contractions of the auricles may occur for every contraction of the ventricle. When laudanum is poured into the heart, the rhythm is quite reversed; for after each pause the ventricle contracts first, and contraction of the auricle follows it. Digitalis and some other poisons cause peristaltic movements in the ventricle; and occasionally some spots in the ventricle continue to pulsate while the rest of it remains firmly contracted and motionless. These effects are probably due to disturbance of the apparatus which connects the different motor ganglia in the heart and causes them to work in unison.

**ARE THE MUSCULAR FIBRES OF THE HEART PARALYSED?**—We test this by applying an irritant to them directly, and seeing whether or not they contract. If the motor ganglia be uninjured, the application of an irritant generally produces a rhythmic contraction of the whole heart; but, if they be paralysed while the muscular fibre is healthy, the irritation only causes a local contraction of the part to which it is applied.

**BLOOD-PRESSURE.**—The blood-pressure depends on two things—1, the activity with which the heart pumps the blood into one end of the arterial system; 2, the rate at which it flows out at the other end into the veins. The rate is regulated by the small arteries and capillaries, which dilate and contract so as to quicken or slow it. The power of contraction is denied to the capillaries by many physiologists; but Stricker has, I think, conclusively shown that they do possess it.

The rapidity with which the blood flows through them does not depend entirely on the width of the capillaries, but also on the pressure on the arteries which is forcing the blood into them. The higher this is, the more rapidly does the blood flow; and in proportion as it diminishes, does the current become slower. From this circumstance we can judge of the force of the heart-beats from the form of the curve which we obtain with the sphygmoscope. When the heart contracts with great force, it drives the blood out of the ventricle into the arteries so quickly that there is no time for much to escape from the capillaries while the systole lasts; and so the tension rises high. This increased tension makes the blood run quickly out of the capillaries, and we have a fall of pressure, rapid at first, but gradually becoming slower as the tension diminishes. This is shown in Fig. 13. When the heart

Fig. 13.

contracts less forcibly, it sends in the blood more slowly, and there is time for a greater quantity to escape by the capillaries during the systole; and the tension does not rise so high. From the tension being lower, the outflow of blood is not so quick; and the pressure therefore sinks more gradually than in the former case. This is represented in Fig. 14. Both of these figures were obtained by connecting a sphyg-

Fig. 14.

moscope with a schema of the circulation such as I have already described, and compressing the India-rubber ball which represented the heart with greater or less force and suddenness; care being taken, however, to empty it completely each time, so that the amount of air sent out should always be alike.

As variations in the blood-pressure may be due to alterations in the activity of the heart or the size of the capillaries, or to both together, we cannot say when it is due to the one and when to the other, unless we can keep one of them constant while we allow the other to alter, or unless we examine them both separately.

**ELIMINATION OF THE ACTION OF THE HEART.**—We may keep the action of the heart tolerably constant, and thus ascertain with considerable exactitude the action of any drug on the exit-tubes—whether they be arterioles or capillaries matters not—by separating the heart from the nerve-centres, and then injecting the drug into the circulation.

**DIVISION OF CARDIAC NERVES.**—This separation can be effected to a considerable extent by dividing the sympathetics, vagi, and depressors in the neck; but it is done much more effectually by dividing

\* Concluded from page 689 of number for December 16th.

the nerves near their entrance into the heart by a fine wire heated by means of a galvanic battery.

As poisons generally produce their most marked effects on the heart of mammals through the nervous centres whose connexion with the heart we have thus severed, alterations in the blood-pressure will be due to changes in the vessels, except in so far as the drug may have affected the cardiac muscle or ganglia. But, just as we obtained the most exact results when we examined the heart altogether apart from the blood-vessels, so we shall probably come to the most satisfactory conclusions regarding the vessels by observing them apart from the heart. You will remember that, during the diastole, the circulation is carried on entirely independently of the heart by the pressure of the blood in the arteries; and, if we can prolong the diastole sufficiently, we shall be able to tell whether the vessels are dilated or contracted by simply seeing whether the pressure sinks quickly or slowly.

If we prevent any blood from being pumped into the aorta by the heart, the arterial system will come to resemble a bottle with a hole in it, from which the fluid which it contains is running. The larger the hole, the more quickly will it run out and the bottle become empty, and *vice versa*; and, in the same way, the more dilated the capillaries are, the quicker will the blood run out of them into the vein, and the pressure sink in the arteries; the more contracted the capillaries are, the more slowly will the blood flow through them, and the more gradual will be the fall of pressure. In the case of many poisons, we may do this by irritating the vagi before poisoning, and seeing how quickly the pressure falls while the heart is standing still; and then repeating the experiment after injecting the poison. If the pressure fall more quickly in the second case, we know that the vessels have become dilated; and if more slowly, that they have contracted. Of course, only those parts of the tracings in which the pressure has been the same are to be compared with each other; but, if we stop the heart long enough, we can always get parts in both which are capable of comparison.

When the poison paralyses the vagus, as atropia does, this method fails; and then we must open the thorax, perform artificial respiration, and put a ligature round the aorta.

**ARTIFICIAL CIRCULATION IN MAMMALS.**—As an animal quickly dies when the aorta is ligatured, it is better to carry on artificial circulation by a syringe through a cannula inserted into the aorta, as Hering and Horvath have done in their researches on the connexion between arterial movement and respiration. This method I have already described. After the blood has circulated once, it may be defibrinated, shaken with air warmed to 40 deg. Cent., and re-injected. Instead of using a syringe, the cannula in the aorta may be connected with the nozzle M, Fig. 6, and the blood put in the flask 3. It can thus be kept at a constant temperature more

Fig. 6.

easily than when a syringe is employed. The pressure may be alternately increased and diminished so as to imitate the beats of the heart by raising and depressing the flask A. This may be done by passing a string over a pulley, and attaching one end to the flask and the other to a treadle worked by the foot. Warm blood has the disadvantage, that it undergoes change and becomes decomposed quickly; and cold blood may, therefore, be sometimes preferred. When cold blood is employed, only the flask which contains the blood is necessary; and it may be raised or lowered in the same way as the other.

**ARTIFICIAL CIRCULATION IN FROGS.**—Artificial circulation may be kept up in frogs by simply inserting a cannula into the aorta, and allowing blood to flow into it from a raised reservoir, as done by Rollett. By using two, as in the experiments on the frog's heart, normal blood may be allowed first to circulate through the vessels; and, the web being put under the microscope, their diameter may be measured; and then poisoned blood may be allowed to flow through them, and any change in their diameter noticed.

**OBSERVATION OF VESSELS.**—The parts best adapted for observing

changes in the size of vessels in mammals are the ear in rabbits and the mesentery. When the mesentery is chosen for observation, the abdominal parietes should be divided; but the peritoneum should not be opened, as changes in the diameter of the mesenteric vessels may be observed through it, and they are thus protected from the disturbing element which the irritation produced by the access of air to them would introduce into the experiment. The vessels in the rabbit's ear are readily measured by a micrometer used with one of Brücke's magnifiers, which is simply a telescope with an extremely short focus. The ear should be held up so as to allow the light to shine directly through it, and the magnifier placed horizontally.

The area of the capillaries may be lessened, and the flow of blood through them retarded in two ways; 1, by contraction of their walls; 2, by pressure exerted on them from without. They may be made to contract by irritation, 1, of the vaso-motor centres, 2, of the vaso-motor nerves, or, 3, of their muscular walls; and pressure may be exerted from without by the motions of muscles or of organs composed of involuntary muscular fibre such as the intestines. The movements of respiration also, as already mentioned, exercise an important influence on the pressure.

**ELIMINATION OF RESPIRATION AND MUSCULAR MOVEMENT.**—The influence both of respiration and of muscular movement may be eliminated by giving the animal curare, and keeping up artificial respiration, before beginning to experiment with the drug whose action we wish to examine.

**ELIMINATION OF VASO-MOTOR CENTRE.**—For the purpose of ascertaining whether the drug has acted on the vascular walls or on the vaso-motor centre, we divide the vaso-motor nerves going to a part before injecting it, and see whether it acts as it would have done had they been undivided. Thus, when we are observing the rabbit's ear, we divide the sympathetic in the neck; and, when looking at the mesentery, we cut the splanchnics before the injection, and see whether the vessels contract or dilate as we have previously seen them do under influence of the poison in animals in whom the nerves were intact.

For the purpose of ascertaining whether the drug acts on all the vessels in the body in the same way that it does on those of the ear or mesentery, we first cut the vagi, sympathetics, and depressors; and then divide the spinal cord between the occiput and atlas, or atlas and axis, so as to sever the connexion between the vaso-motor centre and vessels, and begin artificial respiration. We next note the blood-pressure, inject the poison, and see what alterations it produces. Experiments may also be made by irritating the vagus or ligaturing the aorta.

**ACTION OF SURROUNDING PARTS.**—It sometimes happens, as in the case of physostigma, that the drug produces no contraction in the vessels of the ear or mesentery when their nerves are cut—a fact which shows that it acts on them through the vaso-motor nerves, and not directly on their walls; and nevertheless, when injected into a vein after the cord has been cut, it may cause the blood-pressure to rise very considerably. At first sight, this would seem to indicate that the drug acted on the walls of some vessels in the body, if not on those of the ear or mesentery, directly, and not through their vaso-motor nerves. On examination, however, it is found that the obstruction to the flow of blood through the capillaries does not depend on their contraction, but on the occlusion of a large number of them in the intestine by spasmodic contraction of the intestinal walls in which they are imbedded.

**INFLUENCE OF THE PULMONARY CAPILLARIES.**—It has lately been pointed out by Holmes that when a drug such as ergot, which acts on the walls of the vessels and causes them to contract, is injected into the jugular vein, it has to pass through the pulmonary capillaries before it reaches the systemic ones; and, by contracting them, it will lessen the amount of blood sent into the aorta from the left ventricle, and will at first produce a fall in the arterial pressure, succeeded by a great rise when time has elapsed for the drug to reach the systemic capillaries and cause them likewise to contract.

**USE OF THE SPHYGMOGRAPH.**—For a description of the sphygmograph and the mode of applying it, we must refer to the special works on that subject, such as those of Marey and Sanderson. The indications which it gives are the following. 1. The greater or less pressure which is requisite to compress an artery and stop its pulsations enables us to estimate approximately the amount of pressure within it. The amount of pressure and the rapidity of the pulse help us to form conclusions regarding the motor and inhibitory apparatus of the heart, in the same way as in the experiments already mentioned, though, of course, to a much more limited extent and with much less certainty. 3. The form of the curve, like those in Figs. 13 and 14, shows, in the same way as those of the sphygmoscope, Figs. 13 and 14, the rapidity with which the pressure falls during the diastole; and from this curve and the amount of blood-pressure we can judge of the size of the capillaries.

## REMARKS

ON

THE INSTRUMENTS DESIGNED FOR EXPLORING  
GUN-SHOT WOUNDS,WITH A VIEW TO DETECT BULLETS OR OTHER FOREIGN  
BODIES SUSPECTED TO BE LODGED IN THEM.

By T. LONGMORE, Esq., C.B.,

Professor of Military Surgery at the Army Medical School, Netley.

To obviate these difficulties and sources of fallacy, a surgeon of the French army, Dr. Lecomte, invented an instrument, to which he gave the name of "probe-nippers" (*stylet-pince*). His design was not merely to indicate the presence of a leaden bullet, by bringing away a stain or mark of its presence, but by bringing away a small portion of the lead itself. Such an instrument could not only be used for bringing away a scale of lead, but also a minute portion of paper, cloth, wood, or any other foreign body capable of being cut in a similar manner. If the supposed foreign body were a fragment of bone, it would equally bring away a particle of it. It was evident that, in addition to its other qualities, the *stylet-pince* would require to have its nippers smaller in size than the porcelain knob of Nélaton's probe, with a stem of sufficient length to be passed along narrow sinuses, and at the same time solid enough to bear a certain strain in use. I have ascertained by practical experience that the *stylet-pince* does possess the qualities aimed at by Dr. Lecomte.

The instrument consists of two portions. The first is a central steel rod of small diameter, fixed in an ivory handle at one extremity, and cleft at the other into two small branches, each of which terminates in a little cup-like blade or curette; the second is a slender cannula, which glides backward and forward, but only within a limited distance, along this rod. The central rod is fixed in the handle by means of a side-screw, which can be loosened at pleasure by the surgeon, so as to increase the length of the exposed part of the stem, or to enable it to be removed altogether to be cleaned. The two steel curettes have very fine and sharp edges. They separate from each other by the elasticity of the two little steel branches, of which they are the terminations; but they are easily brought together by a slight pressure, such as that exerted by causing the cannula to glide along the central stem up to them. When they are thus brought together, the two curettes so fit one to the other that, united, they form a small smooth steel knob or rounded extremity, about one-third of the usual size of the china knob of a Nélaton probe.

It will be apparent, from the description, that the gliding of the cannula determines the opening and closing of the curettes: when it is slipped back, the curettes open; when it is pushed forward, they are closed, and form a little hollow globe. There is no difficulty in the manipulation of the instrument. It is inserted with the curettes closed, and it may be used then precisely as the long silver probe in a surgeon's capital case of instruments. When about to be employed for determining the nature of the substance with which it is put into contact, the cannula is drawn towards the surgeon, at the same time that the extremity is retained with an equable and steady pressure against the substance. This movement has opened the curettes. The same even pressure is sustained while the cannula is pushed home, and this causes the curettes to be brought together again; their edges, as they close towards each other, nipping off a small particle of the substance over which they are moved. The instrument is then withdrawn, and, supposing it to have been brought into contact with an ordinary bullet, a small scale of lead will be brought away enclosed within the cavity of the rounded extremity formed by the two curettes. The glistening surface of the freshly cut shaving of lead will sufficiently indicate its nature. If any difficulty should occur in distinguishing the particle which has been brought away, it can be removed from the curettes, and observation under an ordinary magnifying lens will show what the substance is. The *stylet-pince* is thus a most useful explorer for deciding doubtful cases of lodgment of foreign bodies; it responds as an indicator with even more distinctness than the Nélaton probe in all cases in which that test would be of service, while it answers for a variety of other cases in which the Nélaton probe would give no indication at all.

Electricity was some years ago suggested as a means of detecting lodged bullets and other metallic substances in wounds; and some very ingenious apparatus depending on this agent have been lately contrived for the same purpose. One of the first to experiment upon an electric ap-

pliance of this kind was a French military surgeon, M. Fontan, assisted by M. Favre of Marseilles. A description of the somewhat complicated apparatus employed in these experiments is to be found in the *Gazette des Hôpitaux* of the 29th November, 1862.

The improvements which have taken place in the modern applications of electricity have paved the way for more simple and yet more sensitive bullet explorers. One of these is the invention of Mr. De Wilde, a civil engineer, and is very compactly arranged in a box of small dimensions. The electric action is excited in a suitable cell; the electricity there developed is increased in intensity by the intervention of a multiplying coil; an exploring probe is connected by insulated wires with the apparatus; and the indication, when the circuit is completed by contact of the two points of the probe with a leaden bullet or piece of iron, is given by the striking of a hammer against an alarm-bell. The bell sounds at each interruption and renewal of contact of the points with metal. The exploring probe consists of a long slender tube of smooth vulcanite, containing two insulated needles, the points of which can be withdrawn within the tube, or be made to protrude, at the pleasure of the operator. Altogether it is an effective appliance as an exploring instrument, owing to the strength of the electric current developed, and the marked manner in which the indications are given by the sound of the bell when a bullet or other metallic substance is met with. There is also attached to the instrument a bullet extractor, the two arms of which are insulated, and so arranged that, when they are connected, in the same way as the explorer, with the battery, they indicate the grasping of the foreign body similarly by the sound of the bell. Unless the metal be firmly grasped by both blades, without any other substance intervening, the indication will not of course be given.

Another instrument of a similar nature has been made by Messrs. Krohne and Sesemann of London. The indications of contact with a lodged bullet or other metal are in this instrument afforded by the movements of a galvanometer, and of a fine needle working upon a dial-plate, in the same manner as is seen in the ordinary single needle telegraph. I have experimented with both these instruments, and have found them equally effective in their indications. Attached to the latter instrument is not only a bullet-extractor as well as the explorer, but also a pair of acupuncture needles, for use in cases where metallic bodies are supposed to be lodged in soft tissues, away from any means of approach by a wound or sinus.

A rough but sufficiently effective electric instrument for facilitating the discovery of metallic substances lodged in gunshot-wounds has been made in the following way. The magnet of an ordinary pocket-compass, which has had some turns of wire covered with thread wound round it as an induction coil, is employed for the electric indicator while a piece of copper sheeting, bent round a small plate of zinc, but separated from it by flannel padding saturated with the usual diluted acid, forms the voltaic pile. The exploring instrument is formed by two insulated wires, bound together, but with the points left free. These parts being connected, when the circuit is completed by contact with metal, the indication is given by movement of the magnet of the compass.

Lastly, the endoscope has been suggested for use in exploring for foreign bodies in wounds. Dr. Fenger of Copenhagen, in 1869, made some experiments with the instrument on horses, and came to the conclusion that pieces of cloth in wounds, or bullets driven into bones, could be seen by its means. Dr. Fenger has stated that during the late war he was enabled in several instances, on examining wounds some weeks after they had been inflicted, to see their interiors distinctly by means of the endoscope, without causing pain, hæmorrhage, or any subsequent irritation, in consequence of the introduction of the instrument. I have no experience of such an application of the endoscope, and can hardly think that, with so many other effective appliances available, it is likely to be turned to much practical account in this direction.

It must be sufficiently obvious that several of the exploring instruments just described are not suited for use in the field. The circumstances of gunshot-wounds themselves, as they are ordinarily presented shortly after their infliction, do not render such instruments necessary; nor are some of them—as the electric explorers for example, which may be easily disarranged—suitable for use in the places where the wounds resulting from battle are usually treated during their earliest stages. But it has not been the purpose of these remarks to discuss either the nature or circumstances of the wounds in which instruments of this kind may be specially serviceable; their object has been only to describe the instruments available for exploring for foreign bodies in cases where the exploration is decided to be advisable. It is only right to remark, however, in conclusion, that even in such cases there must be a limit to search. This limit must depend on the circumstances of each particular case, and must be decided by the judgment and tact of the

\* Concluded from page 746 of last number.

responsible surgeon. As a general rule, it may be stated that, whatever may be the reasons for concluding that a bullet or any other foreign body has lodged in or near a gun-shot wound, if, after search by the finger in cases where a digital examination is practicable; after external manipulation and observations made in varied postures of the part of the body concerned; after attention has been given to indications derived from the patient's sensations; effects of pressure upon, or injury to, nerves; and, lastly, after a moderate but careful exploration by one or other of the exploring instruments just described, if, after these steps have been taken, the site of the lodgment be still not ascertained, more especially if the patient be suffering pain, or is in an exhausted condition, the exploration should be at once discontinued. The continuance of the search will not merely add to the weariness and distress of the patient, but, if the several proceedings above-named have been properly carried into execution, it is not likely to be attended with a successful issue. The foreign body will probably have passed beyond or out of the field of exploration, or have become deeply impacted in bone, or entangled among tissues, where it could only be discovered by an unjustifiable amount of meddlesome and injurious disturbance of the structures implicated. We must rest in hope that, either during the process of supuration, or under the influence of muscular actions, or by gradual approach toward the surface, the escape of the foreign body, whatever its nature, whether hard or soft, smooth or rough, organic or inorganic, may be eventually effected without such risks; or, if it be of a favourable kind and form, such as a leaden bullet is when its normal shape is retained, and if it be not in contact with a nerve, bone, or other important organ, that the wound may heal favourably, notwithstanding its presence, the foreign body becoming encysted, and remaining lodged without causing either pain or mischief for many years afterwards.

### HYDRATE OF CHLORAL IN PUERPERAL CONVULSIONS.\*

By J. G. SWAYNE, M.D.,

Physician-Accoucheur to the Bristol General Hospital.

**CASE I.**—On October 26th, 1870, Mr. Taylor requested me to see Mrs. H., living in Kingsdown, Bristol. She was a primipara, and from his account, had had albuminuria with oedematous extremities for about three weeks. For this he had purged her and given diuretics up to the time when symptoms of labour set in, accompanied with convulsions. I saw her first at 7.30 P.M. She had then had two convulsive attacks—the first at six, and the second at seven o'clock. Mr. Taylor had given her calomel and jalap, and applied a sinapism to the back of the neck. The breathing was slightly stertorous, but she was not wholly unconscious. Before the fits came on, she said that she saw "beautiful green things floating in the air." On examining, I found the os uteri dilated to the size of a crown-piece, and the head presenting. The membranes were unruptured, and there were scarcely any labour-pains. We bled her to fourteen ounces. Immediately after this, at eight o'clock, another fit came on. When it was over, we injected into the rectum thirty grains of chloral dissolved in three ounces of water. The pulse, which had previously been about 70, was now about 120. She was at first rather restless, but soon became more conscious, said her headache was better, and fell into a tranquil sleep. We then left her, with instructions that if any fresh symptom came on, Mr. Taylor was to be summoned immediately. Next day, I received a note from Mr. Taylor, in which he stated that she remained in the tranquil state in which we left her for nearly an hour, when labour-pains set in with regularity, and went on until 3 A.M., when he was sent for; and, on examining, found the head in the pelvic cavity, and a fairly good pain; but with the second pain after his arrival, she had a convulsion as severe as that we witnessed. He immediately applied the forceps and delivered her as quickly as possible, when he found, to his surprise, that there was a second infant. However, a foot presented, which he soon brought down, and promptly delivered the child. There was a considerable hæmorrhage at the removal of the placenta, but she was not very much exhausted, and he left her feeling comfortable. Mr. Taylor added that, "she is to-night cheerful, with a pulse of 100. So far, we may congratulate ourselves on the termination of a somewhat unpromising case. Your chloral had a most decidedly soothing effect, and I fancy its topical irritant quality may have had a reflex influence on the pelvic nerves." I may add that the patient went on favourably, and ultimately made a good recovery.

**CASE II.**—On March 24th, 1871, I saw, in consultation with Mr. Wine, Mrs. R., aged 25, living in Broad Street, St. Philip's, Bristol.

She had had two children previously with easy labours. About five days before the present labour, she was frightened very much (because one of her children was nearly run over), and felt no fetal movements afterwards. Mr. Wine saw her first at 3 A.M. on March 25th. The os was then slightly dilated, and the pains feeble. She then had a convulsion for the first time, and afterwards dozed off into a snoring sleep. Mr. Wine went home for three grains of calomel, which he gave her. He came again at 10 A.M., and found that she had had six fits since he last saw her. On examining the bed, he found that she had given birth to a dead child, which was quite rigid. About 11 P.M. on March 25th, she had a very bad epileptiform convulsion. After that (about twelve o'clock) she had some fits of a more hysterical character, accompanied with screaming. When I saw her at 1 P.M. on March 26th, she was lying in an almost insensible state. The pupils were scarcely affected by light; but the breathing was not stertorous. Pulse 86. We drew off about twelve ounces of dark coffee-coloured urine. This was highly albuminous, and became almost solid when heated. We gave her thirty grains of chloral by injection. At 10 P.M. I saw her again, when Mr. Wine told me that she had another fit about half an hour after the chloral was administered, and then another very long one about half an hour after that, and then none for two hours until 6 P.M., after which she had seven rather violent ones. Although her pulse was rather weak, we bled her at 10.30 P.M. to twelve ounces. She had a fit about twenty minutes before the bleeding, and another about an hour afterwards. There was then a complete cessation of them for three hours until a quarter to 3 A.M. on March 27th. From that time up to 8 A.M., the fits returned, and she had as many as twelve. I saw her at 11.30 A.M. on March 27th. She had then been quiet, and had slept for more than three hours without any fits. The pulse was 136. The urine now showed no trace of albumen. The pupils were slightly affected by light, and she was able to take a little milk and brandy, though scarcely sensible. We ordered her thirty grains of chloral, to be repeated if necessary in six hours. She took the first dose at 2 P.M., and (by a mistake of the woman in attendance) the second dose at 4 P.M., and thus one drachm of chloral was administered in two hours. I saw her at 10.30 P.M. There had been no return of the fits, but she was lying in a very prostrate condition, with a pulse of 144, and respirations 36 in the minute. I was summoned early in the morning of the next day (March 28th), because Mr. Wine, from certain symptoms, apprehended an attack of abdominal inflammation. The abdomen was tympanitic and somewhat tender to the touch. There had been no more fits, but she was lying in a very prostrate condition, and was scarcely sensible. Pulse 125; pupils slightly affected by light. As she had not yet had much stimulus, we ordered her a dessert spoonful of brandy every two hours. She was able to take strong beef-tea and milk very well. On March 29th, she was much better, able to answer questions, and becoming conscious. Pulse 108; appetite good. I did not see her after this, but Mr. Wine reported to me that she made a good recovery, with the exception of considerable headache, which lasted about a week.

**REMARKS.**—I have brought forward these two cases of convulsions rather with the view to record my own experience, as far as it goes, with respect to the use of a comparatively new medicinal agent in this formidable disease, than because they furnish any very conclusive proof of the value of the remedy. I have the highest opinion of the efficacy of bleeding in puerperal convulsions, and have shown from time to time that it has a greater power than any other remedy in removing the albuminuria which is probably at the root of this affection. I did not, therefore, in either of the two cases just mentioned, feel justified in relying solely on hydrate of chloral and omitting to bleed; and, on this account, the cases are not so conclusive as to the value of chloral as one could wish. In the first case, however, the chloral, when given after bleeding, seemed to have a very tranquillising effect, and the result, perhaps of both, was that there were no more fits for about eight hours, when they came on again with the more severe expulsive pains of the second stage, and were at once relieved by delivery. The great distension of the uterus from the presence of twins had probably some share in causing the convulsions. In the second case, the convulsions appeared to be chiefly due to the very unnatural condition of the urine; for they were not relieved, but rather became worse after delivery. Chloral was then given to the amount of thirty grains, and there was a cessation of the fits for about two hours. The woman was bled after the fits returned, and they then ceased again for three hours, though not immediately after the bleeding. After that the fits returned, nearly one in every hour, and then appeared to cease spontaneously as soon as the urine was free from albumen. Soon afterwards, she took, partly by mistake, a double dose of chloral (about one drachm in two hours), and there was no return of convulsions; but this powerful dose of chloral appeared to add very much to the previous prostration.

\* Read before the Bath and Bristol Branch, October 1871.

From this, however, she soon recovered, and ultimately did well. From what I have seen of the action of chloral in puerperal convulsions, I am disposed to think that its action is similar to that of chloroform, but that it is more steady and persistent in its effects, and that it is much more manageable, because we can regulate the dose with much greater nicety. Although it ought not to supersede bleeding, it is yet a most valuable adjunct to it, and is, in fact, the best antispasmodic we can employ in such cases. I believe that the dose required to produce a decided effect must be large—at least forty grains at a time—and this may be repeated in three or four hours. I lately saw a case of puerperal mania, accompanied with much excitement and entire loss of sleep. This restlessness was quite unrelieved by full doses of opium, and was very little affected by thirty grains of chloral. We then gave forty grains of chloral, and repeated it in two hours, and the result was that the woman had six hours of tranquil sleep, after which she immediately began to improve until she made a good recovery.

# ABSTRACT OF A CLINICAL LECTURE ON A CASE OF PURPURA, FOLLOWED BY CONVULSIONS, IN A YOUNG CHILD.

*Delivered at King's College Hospital, November 30th, 1871.*

By W. O. PRIESTLEY, M.D.,

Professor of Obstetric Science in King's College; Obstetric Physician to King's College Hospital.

GENTLEMEN,—We have had some interesting cases in the Children's Ward since my last lecture. One little child has died after an illness with a somewhat curious and instructive history. She was thirteen months old, and suffered from purpura. This affection, which commonly occurs in cachectic children, very closely resembles the blood-disease called scurvy, from which sailors suffer when, during long voyages, they are deprived of fresh vegetables. There are large or more minute deep purple spots in the skin scattered over the surface of the body. The little child, the notes of whose case have been taken by Mr. Eardley Wilmot, was named Maud Isabel Gingall, and she had been in the Pantia Ralli Ward suffering from the same condition in the latter part of August, and, after a course of chalybeates, was discharged cured. On September 21st she was again brought to the hospital covered with fresh purpuric spots, and with extensive ecchymosis over the left eyelid and cheek, and also of the vulva. These latter injuries were supposed to have resulted from a fall from a perambulator. About the joints particularly were large patches and many little dark spots, as if they had been pricked with a needle, and thus blood extravasated. She was placed on generous diet, with wine, and to have the following draught three times a day.

℞ Ferri sulph. gr. iij; acid. sulph. dil. ℥ ii; syr. simp. ℥ x; inf. calumb. 3j.

It is necessary to distinguish the spots of purpura from the ecchymosis produced by a blow or a fall. When a child in ordinary health has received a blow, the place may blacken in consequence; but, ere long, gradual changes of colour take place in the spot; the discoloration becomes ultimately purple, green, and yellow, and gradually disappears, the part perfectly recovering its flesh-tint in some days. In this child the deep colour did not pass away in the ordinary fashion, but remained persistent—thus proving that, if the child had been bruised at all, there was some faulty condition of health which interfered with the recovery of the ecchymosed parts. As the large doses of sulphate of iron did not seem to be producing any good results, on the 9th October a drachm of lemon-juice was ordered to be given three times daily. Lemon-juice is given to sailors suffering from scurvy, and proves to them of the greatest service, answering as well as green vegetables. Dr. Budd, it is true, has pointed out that there are some important differences between purpura as we see it on land and sea-scurvy, and that the former is less benefited by lemon-juice; but it was thought desirable to try the effect of lemon-juice in this case by way of experiment. On October 14th there was, however, no improvement; a fresh crop of spots had appeared on the legs and abdomen; and the child was ordered 5 minims of tincture of perchloride of iron, 2 minims of dilute hydrochloric acid, with syrup and water, three times daily. In the evening of that day she was seized suddenly with very violent unilateral convulsions; the left side, leg, arm, and face, being thrown into violent spasmodic action. The left pupil remained normal, while the right contracted. She remained in an unconscious state for fourteen hours, taking no food or medicine; the temperature was 103 deg. Fahr., and the pulse 150. One ounce of brandy was ordered daily, and a purge to clear out the bowels. For the next four days the child remained in a semi-con-

scious state, taking very little food and sleeping little. The eyes were fixed and turned inwards, and the pupils were now dilated and immoveable. On the 19th October she had another fit, similar to the preceding, but less violent. On October 23rd, diarrhoea, with bloody stools, set in, after which she gradually regained consciousness, and seemed much better, though still very weak, and her appetite was defective. It was then observed that no paralysis remained in the side affected. She continued much the same to November 11th, but was obviously losing flesh and growing weaker. Her weight was only 13½ lbs. She was ordered one drachm of cod-liver oil three times daily. On the above date a third fit came on, and the diarrhoea increased. The temperature was 102 deg. Fahr. From the effects of this fit the child never rallied. As a further complication, bronchitis set; the chest became full of moist râles and coarse crepitation; but there was no dulness present. Some new purpuric spots appeared on the legs. She was ordered quinine, and the brandy was doubled. On the 16th November she was evidently much weaker, and seemed to be sinking. Her weight now was only 12½ lbs. The pulse was almost imperceptible, and the lungs were choked with mucus, the child having no power to cough. The breath was very offensive, and there was occasional vomiting, although she took very little food. The brandy was increased to three ounces. She died on the 19th October, at 12.45 P.M.

Now, gentlemen, some may naturally ask, What relation has the purpura in this case to the occurrence of the convulsions at the later period? The investigation of this point becomes an interesting pathological study. I may state at once that I believe this child had the convulsions as the result of cerebral hæmorrhage. This is not altogether infrequent in young children; and yet it is very rarely followed by paralysis, as in the adult. When an adult is stricken with apoplexy, the immediate effect is a convulsive seizure, followed by permanent and incurable paralysis; but the hæmorrhage in the adult is commonly into the substance of the brain rather than into the membranes, and, as a consequence, destruction of nervous substance is the greater. In young children, on the contrary, although we get cerebral hæmorrhage as in the adult, yet the bleeding much more frequently takes place into the arachnoid cavity than into the brain-substance.

Sunstroke is a common cause of cerebral hæmorrhage in young and healthy children. When a child is much exposed to the sun in this country, and more especially in warm climates, it is sometimes seized with giddiness and convulsions, and probably dies. It has been found that in these cases there has been a large amount of congestion in the blood-vessels of the brain and its membranes, leading to extravasation of blood. But we also find cerebral hæmorrhage occurring in children of very feeble condition, imperfectly nourished, and cachectic. There can be very little doubt that, in the case of the little child whose history I have read to you, what occurred in the capillaries of the skin took place to a greater degree in the interior of the cranium. Blood was poured out also on the surface of the mucous membrane of the intestine, and caused bloody stools. When the convulsions took place, small vessels were probably ruptured on the surface of the brain, and extravasation took place into the cavity of the arachnoid. More than one rally took place, and the child might possibly have recovered but for the fresh complications which sprang up. When chest-symptoms were developed, the child could not cough up the mucus, and the bronchial tubes became so choked that she rapidly sank. It is much to be regretted that the friends would not permit a *post mortem* examination, else we might have been able to confirm the diagnosis of cerebral hæmorrhage made during life.

I may here say a few words to you in reference to the diagnosis of cerebral hæmorrhage, and warn you that you must not jump to the conclusion that cerebral hæmorrhage has occurred in all cases where there are convulsions. Convulsions come on from teething and other reflex sources of irritation. When there is no cerebral hæmorrhage and no true organic disease of the brain, and in cases of strumous meningitis or inflammation of the membranes of the brain—an affection which in some part of its course is pretty sure to be attended by convulsions—we have the antecedent history to guide us. In those instances where cerebral hæmorrhage takes place from exposure to the sun, we have the fact of the exposure and the suddenness of the attack almost diagnostic. Then, absence of teething, and of the history of acute hydrocephalus, is also valuable as further evidence. In strumous meningitis there is, generally, preliminary and persistent vomiting: the bowels are either confined or very much relaxed for some time previously to the attack; the child has headache, grows fretful and impatient; the fontanelle, if open, is prominent and throbbing, and the vessels of the conjunctivæ and scalp are probably notably congested. There is in most instances, indeed, though not in all, a gradual development of the symptoms, convulsions being among the latter phenomena. In the case before us there were no such symptoms; but there were indications of previous

cachexia, with spontaneous extravasations of blood in the form of purpuric spots over the surface of the body; and the sudden supervention of convulsions, without previous signs of brain-mischief, pointed clearly to the inference, that, just as blood had previously escaped into the meshes of the skin, so now it has been in greater or less quantity poured out on the surface of the brain.

In treating this child, the all-important indications from the first were, so to improve its general health and effect those salutary changes in the composition of its blood, that the tendency to purpuric extravasation should be removed. With this view it was warmly clad, well and carefully nourished, and full doses of sulphate of perchloride of iron were given; these preparations, besides being powerful tonics, having also the character of being styptic remedies. The addition of lemon-juice did not seem to have any marked effect on the blood-spots. When cerebral hæmorrhage was believed to have taken place, there was not much to be done beyond keeping the head cool, the bowels open, and the giving of such food and stimulant as could be swallowed.

When a child, otherwise healthy, and whose pulse is full and bounding, is stricken with symptoms which you believe to be due to cerebral hæmorrhage, you need have no hesitation about employing a few leeches to the scalp, and applying ice to the head. In children reduced by previous illness, or rendered cachectic, as in Gingall's case, great care must be exercised that more strength is not expended by bleeding, and that further depression is not produced by too great cold. Rather we must endeavour to keep the circulation quiet by less potent measures, and support the strength by food and stimulants in such a way that, while no fresh and strong impulse is given to the circulation in the direction of the points where blood has escaped, we may yet give the little patient a chance of rallying, if it escape the immediate effect of the shock which has in the meantime overwhelmed it.

### CASE OF POISONING BY VERMIN-POWDER CONTAINING STRYCHNIA.

By FREDERICK T. ROBERTS, M.D., B.Sc.,  
Assistant-Physician to University College Hospital.

I was hastily summoned on Monday afternoon, November 13th, to the University Hotel, where a man had been found dead in bed. He had been staying there about a week, living very irregularly; and had come in on the previous evening about half-past eleven, and immediately retired to bed. It was his custom not to get up until late; but, as he had not appeared by 2.30 P.M., the waiter went to call him, and discovered that he was dead.

When I saw the body, I noted the following appearances and conditions. It was that of a well-made muscular man, rather stout, and apparently about thirty-five years of age. He was lying on his back, with a perfectly calm expression of face, the lips being slightly apart, the chest partly exposed, and the hands clutching the bedclothes, which, however, were tucked in, and scarcely at all disturbed. The trunk was still warm, but the extremities and face were quite cold. There was universal and marked rigidity, the limbs being quite straight—the condition, in fact, being just that produced by a strong rigor mortis. Some evidences of congestion were observed in dependent parts; but the face and uppermost parts of the limbs and trunk exhibited no discoloration. The pillow presented a patch as if of dried perspiration, where the head lay, and for some distance around it. There were no signs of any vomiting. On searching the room, I found a tumbler on the washing-stand containing a little moist sediment, of a bluish-green colour; and a slight white crystalline-looking film could be seen lining its upper part. In the fire-grate were some envelopes, marked "vermin-killer" and "muricidane", but containing nothing. There were, however, with these some pieces of newspaper, in which was a light blue powder. Nothing else was discovered, except plenty of evidence that the man had been in distress. Of course I took the glass and papers away with me, and immediately sealed them up.

A *post mortem* examination was made on Wednesday, November 15th. The body was much decomposed, but rigor mortis still existed in the legs and hands. *Post mortem* congestion was very marked. The muscles were dark and well nourished. On opening the head, the veins and sinuses were seen to be overloaded with fluid blood; and the brain itself was congested, with some excess of sanguineous serum in the ventricles, evidently *post mortem*. The lungs were much congested posteriorly, but otherwise healthy. The heart was flaccid and flabby, its right cavities containing a very little fluid blood. The blood generally showed no tendency to coagulate. The stomach contained about

two ounces of a thick brown liquid, and two or three small fragments of meat and potato, with no particular odour. The contents were removed, and sealed up in a bottle. The stomach and intestinal mucous membrane appeared very pale, and gave no evidence of any irritation. The other organs were simply congested.

An inquest was held, and adjourned, in order that a chemical analysis might be made, as it was impossible to give any opinion as to the cause of death from what had been observed. Professor Barff, of the Royal Academy and University College, performed the analysis, and subjoined are the notes, furnished by himself, of the processes he made use of, and their results.

"The residue in the tumbler was treated with hydrochloric acid, filtered, and the filtrate submitted to the action of sulphuric acid and bichromate of potash. The colour-reaction for strychnine was immediately produced. When tasted, the filtrate was intensely bitter; and a portion of it produced tetanic convulsions in a frog after two minutes, and caused death in less than five minutes. Emprostotonos was well marked, the back being arched upwards, and the frog resting on his toes and mouth. Relaxation took place before death. Half the contents of the stomach were submitted, after acidulation with hydrochloric acid, to dialysis. The liquid outside the dialyser was evaporated, and gave indications of the presence of strychnine with the colour-test. The other half was divided into two parts, one being treated by Stas's method; the other by my own, which consists in warming over a water-bath for about an hour with dilute hydrochloric acid; then filtering, and shaking up the filtrate with alcohol, and saturating with normal carbonate of potash. The alcohol containing the alkaloid floats to the top, and is drawn off with a pipette. After evaporation, the colour-tests were applied, and the results were obtained much more distinctly than by Stas's process. From experience I can state that the use of tartaric acid to dissolve the alkaloid out of the organic mass is very objectionable, as, at the temperature of 100 deg. C., that acid is, in the presence of the substances contained in the stomach, decomposed, and forms caramel, easily detected by its smell. I should mention that, in performing the reaction with alcohol and potassic carbonate, the mixture should be warmed for a time in a water-bath; and time should be allowed—say three or four hours—for the solid matters to settle out of the alcoholic solution. There were three papers, containing a light blue powder; and in one of these ample evidence of the presence of strychnine was obtained. The other two, however, did not contain any."

REMARKS.—It has appeared to me desirable to publish this case, more on account of its medico-legal interest than anything else. There is not the least doubt that death resulted from poisoning by strychnia, as this was discovered in the tumbler in abundant quantity, also in the stomach-contents, and in one of the powders; while the *post mortem* examination revealed nothing in any of the organs that could account for sudden death. Nor was there any reason to suspect otherwise than that the man had taken it himself. Had there been any suspicion of foul play, there were some points about the case which might have given rise to a difficulty. First, it might have been a question whether it were possible for a man to endure the severe pains which attend the tetanic spasms of strychnia-poisoning without making some disturbance and seeking for help; secondly, whether these could have occurred without producing more displacement of the bedclothes, etc. That such may be the case, is proved by this instance; and the probable explanation is, that he took a large dose, which, owing to the empty state of the stomach, was rapidly absorbed, and led to a correspondingly rapid death, so that his sufferings were of short duration. It is to be noted, also, that the expression of the face was quite calm; and that there was no distortion of the body, which, however, was extremely rigid. This, of course, was due to the relaxation of the muscles, which occurs soon after death in cases of strychnia-poisoning, and the subsequent speedy setting in of rigor mortis. A congested appearance is stated to be present in various parts—in these cases, the result of the spasms; but I only observed it in dependent parts, and it appeared to me to be merely *post mortem*, which had come on rather rapidly, owing to the fluid condition of the blood. The patch of dried perspiration on the pillow was of some importance, as there is free sweating in connexion with the spasms caused by strychnia. The *post mortem* examination revealed nothing more than the absence of any organic lesions, or signs of irritant poisoning; with a somewhat congested state of the organs generally, and a fluid state of the blood; the heart, however, being nearly empty and flaccid.

I would call special attention to the observations of Professor Barff on the analysis of the contents of the stomach, as this gentleman has devoted himself particularly to this subject.

# CASE OF FÆCAL ACCUMULATION (NOTWITHSTANDING DAILY EVACUATION), CAUSING VIOLENT NEURALGIA IN RIGHT LOIN.\*

By C. J. GIBB, M.D.,

Consulting-Surgeon to the Newcastle Infirmary.

ABOUT a month ago, a gentleman living in the country requested me to visit his wife, a very healthy middle aged lady, who had been seized suddenly, three days before, with severe pain in the right loin as she sat at dinner. The pain lasted through the greater part of the night, and left her quite well, as, indeed, she had always been for years before. It recurred, and left again as suddenly, on three other occasions during the two succeeding days; and on the last occasion, the night preceding my visit, it had continued during the whole night in a very excruciating form, without relief from the hot applications and mustard poultices which had previously given her relief.

I found her in bed, to all appearance quite well, as the pain had left her a few hours before. There was no constitutional disturbance. Her tongue was clean, and pulse 68. The pain had been most acutely felt to the right side of the backbone at the last rib, and had shot about from there down the lumbar muscles to the crest of the ilium. It had been of a dull, aching, sickening character, with occasional paroxysms of a more acute lancinating kind. The skin was blistered of a scarlet redness by mustard, the mustard having remained upon the skin for some hours without her even feeling its presence, so acute had been the internal pain. Firm pressure detected under the rib a slight tenderness; but in all other respects the region in which the pain had existed was to all appearance quite normal. The urine was pale, and had passed freely; and, concluding that the kidney could not therefore be the source of the pain, I requested permission to examine the abdomen. There I found slight tympanitic distension, extending from the right iliac bone and groin below to the umbilicus above; but no heat, nor any tenderness or uneasiness on pressure. Indeed, she was not aware that there was anything unnatural the matter with her in the tympanitic region. Questioned as to the condition of her bowels, she stated that they were quite natural; that, although she had taken two opening pills every night since her illness commenced, she had only had the one usual daily morning evacuation which she had been accustomed to have all her life; indeed, that she never required to take the least medicine, as her bowels always acted after breakfast, and the pills had made no difference. That morning's motion had been removed, but was reported to have been healthy. In answer to the inquiry of the husband, I said the cause of the pain appeared to me to be obscure. From its intermittent character, it must be a form of neuralgia, as there was no evidence of the least inflammation; and, although there was no irregularity of the bowels, there was probably some irritation of the head of the colon, from the tympanitic distension that existed there; and the pain in the lumbar nerves might arise from it. I ordered her to remain in bed; to continue the warm poultices; to take two more aperient pills; and, in the absence of castor-oil, to secure free evacuation by Seidlitz powders or an enema, if necessary.

On the following morning, I found that the pain had twice recurred for two or three hours together. There had been two slight motions, loose, but not watery, which, contrary to order, had been removed. In other respects she was the same. She was ordered again to take the pills, and follow them up with castor-oil.

The next morning—the fifth of the attack—she had again been exceedingly ill with the pain for many hours. The oil had caused sickness, and repeated vomiting of a bitter yellow bilious fluid had followed. The skin was cold; and the pulse rather weak, but otherwise natural. There was no tenderness of the abdomen, and the slight tympanitic distension remained about the same. She had taken six pills, and used a soap-and-water enema. The enema had brought away about half a pint of loose dark chocolate-looking fecal matter, with a few small hard pieces intermixed, the whole having a most pungent and foul putrid smell. She was ordered a calomel purge, to be followed by repeated enemata, champagne, and effervescing drinks; and opium to secure her sleep, if the pain should recur at night.

On the sixth morning she was, on the whole, somewhat better. The vomiting had only recurred two or three times; the pain twice severely. One grain of opium, thrice repeated, had secured her some sleep during the night. The tympanitic state of the right iliac region remained; and she had passed nearly a chamber-potful of the same foul dark knotty motions. She was ordered to repeat the castor-oil and enemata, and again to use the opium at night, if necessary; all food

to continue liquid; and the warm applications to be repeatedly applied.

On the seventh day, she was greatly relieved. There had been no sickness; and, although the pain had slightly recurred during the previous afternoon, and again during the night, two grains of opium had given speedy relief. The bowels had been frequently moved; and there was a chamber-potful of the same dark offensive-smelling liquid, but no formed pieces. The tympanitic distension was sensibly less. She was ordered a couple of aloetic pills at night, a Seidlitz powder in the morning, and liquid food.

On the eight day, she was rather weak, but otherwise well. There had been no return of the pain—only some slight uneasiness the previous afternoon, quickly relieved by a poultice. The tympanitic distension was quite gone; and the watery motion, which had followed the Seidlitz powder taken in the morning, had quite lost all that pungent putrid odour of the preceding days, and was of the ordinary yellow straw-colour that ensues after repeated loose motions. She was now told to consider herself well, and gradually to return to her ordinary diet, etc. Some pills of aloes and nux vomica were ordered to be taken every other night for a week or two; and she was enjoined for the next few months to take care to secure free relief from the bowels at least once a week by some gentle aperient medicine.

It is curious in this case that the collection of fecal matters should become putrid and set up the irritation and pain, without any noticeable change of health or constipation of the bowels. It is singular, likewise, that violent relapsing neuralgic pain in the loin should have been the only perceptible symptom for the first few days. No doubt the pain was a colic pain of the colon, reflected into the loins. At any rate, it continued as long as the colon was required to contract on the putrid fecal mass, and disappeared at once as soon as the straw-coloured evacuations proved the colon to have completely emptied itself of the irritant matter.

## A NOTE ON THE USE OF ALCOHOL IN HEALTH AND DISEASE.

By J. W. EASTWOOD, M.D. Edin., M.R.C.P. Lond., Dinsdale Park Retreat, Darlington.

To those who, like myself, have been trying for years to oppose the indiscriminate use of alcohol medicinally and dietetically, it is very gratifying to find that many influential medical men have been induced to adopt views similar to those which I have long advocated. It has been very discouraging to the few to find how lukewarm the profession has been on this subject, and this I can say from long personal experience. In August 1870, I read a paper on "Intemperance in its Medical and Social Aspects" at the annual meeting of the Association at Newcastle, which was printed in the JOURNAL for January 28th, 1871, and I endeavoured to obtain a committee to inquire into the value of alcohol as a medicine and an article of diet. I did not succeed in this, though Dr. Rumsey, Dr. A. P. Stewart, Dr. Morgan, Dr. Ransome, and others were willing to take part in such an inquiry. At the Plymouth meeting I had promised another paper on the subject, but was prevented from attending. This was the less to be regretted, as Dr. Rumsey would not be present, and Mr. Dalrymple, M.P. was in America. Dr. A. P. Stewart made some useful remarks on the question in his address at the Public Medicine Section. I hope at the next meeting at Birmingham more good will be done, and a large number of those interested in so important a subject will be brought together. I have already prepared a general statement of the question, with numerous facts from our hospital and asylum reports, to show how widely different is the practice of the leading medical men in the use of alcohol; and I shall be glad of any information which will assist the object in view. Until a majority of the profession take up the matter, we cannot expect to see any alteration in public opinion; and I quote a paragraph from the paper alluded to, as to the scope of an inquiry such as I propose. "The subject of intemperance should be fully examined in a scientific and humanitarian spirit, and the public should be taught, on medical authority, what is the true position of alcoholics in relation to health and disease."

I can only repeat that, in my opinion, total abstinence has failed in producing any considerable amount of good, which has been confined to individual instances. Unless the profession act in the matter, the public will be beforehand with us, and compel us to do something more than what isolated individuals are capable of performing. It is desirable that copies of the declaration already made be sent to every member of the profession for signature, and I will willingly commence a subscription for the purpose by contributing a guinea. I shall also be glad to be at any trouble in collecting a suitable fund.

\* Communicated to the Northumberland and Durham Medical Society.

## CLINICAL MEMORANDA.

COMPLETE AMAUROSIS AFTER CONVULSIONS  
OCCURRING DURING BRONCHITIS.

SARAH ANN H., aged 3 years, rather plethoric, and suffering from slight bronchitis, was seized on October 27th last with severe convulsions. Upon my arrival, I found her lying apparently dead, there being no pulse, and no impulse of the heart perceptible, nor respiration. I immediately adopted Silvester's method of resuscitating asphyxiated persons; and, after some time, succeeded in restoring her. When consciousness returned, she was found to have slight paralysis of the right arm, and total loss of vision. There were no other signs of pressure. The use of the arm was regained in a few days; but the amaurosis remained complete and without any improvement until December 3rd, when it was perceived for the first time that the child noticed the light of the gas. Since that date, vision has been gradually increasing. No alteration was made for the first week in the treatment, which was directed to the chest-symptoms. As soon as these subsided, she was placed under a course of solution of bichloride of mercury, iodide of potassium, and tincture of nux vomica in small doses, with repeated small blisters behind the ears. On December 16th, the pupils continued rather dilated; they were equal, and acted feebly under strong light, as from the first; but she could now discern any object placed near her.

E. BUCKNILL, M.D.

Rawtenstall, Manchester, December 22nd, 1871.

## OBSTETRIC MEMORANDA.

## EARLY RUPTURE OF THE MEMBRANES.

ALL men engaged in obstetric practice must have observed cases similar to those reported by Mr. S. M. Bradley and Mr. E. Norton, where the membranes have ruptured some long time before the full period of utero-gestation. It has occurred to me that one explanation of them may be an alteration in the normal axis of the gravid uterus—it being more nearly vertical than horizontal in the upright position of the body. The uterus makes with the horizon an angle of about 30 degrees. If this be altered during pregnancy from any cause—e.g., increased resistance offered by the abdominal parietes—then the lower part of the organ (to quote Dr. J. M. Duncan), “the part least supported, and perforated by the os, would be liable to be subjected to the pressure of a column of liquor amnii of about twelve inches in height, or equal to the longest diameter of the uterus. By inclining the organ from the vertical position, the vertical height of the column of water is diminished, and with it the amount of the fluid pressure on every part of the walls of the uterus”.

THOMAS SAVAGE, M.D., F.R.C.S.,

Surgeon to the Birmingham Hospital for Women, and  
to the Birmingham Lying-in Charity.

## PARALYSIS DURING PREGNANCY.

Dr. MADGE will find in the *Obstetrical Transactions* for 1867, p. 12, a case which I reported, peculiarly like that appearing in the *JOURNAL* for December 16th. In my case, Dr. Eastlake and I were able to satisfy ourselves by means of auscultation that pregnancy existed; and I would suggest that, in all cases of doubt, the stethoscope should be used in search of a fetal heart.

The opinions of Dr. Radcliffe in Dr. Madge's case, and of Dr. Sieveking in mine, are peculiarly coincident; and the similarity between the cases holds in many other respects. My patient was a Mrs. S., aged 38, stout and robust. There was never any albumen in the urine. She was delivered of a dead child, and perfectly recovered without any galvanism.

These cases are rare, interesting, and not thoroughly understood. We require more light on the subject; and nothing can so well clear up such difficulties as publication and comparison of cases. It seems pretty certain that albuminuria is not a *distinguishing* feature, as Dr. Churchill supposed. It is probable that the strychnine in my case, and the ergot in Dr. Madge's, was the cause of the death of the fetus *in utero* and premature delivery. I consider that these are cases of reflex paralysis, the irritation extending from the uterus to the nervous centre; and that the recovery of the patient is due to removal of the exciting cause by delivery in most cases, while in a few relief or modification has been obtained by treatment, or could be accounted for in other ways.

PERCY BOULTON, M.D.

Seymour Street, December 17th, 1871.

## REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN  
THE HOSPITALS OF GREAT BRITAIN.REPORT ON THE TREATMENT OF SCROFULOUS  
ABSCESS OF THE CERVICAL GLANDS.

[Continued from page 728 of number for Dec. 23rd.]

## THE LONDON HOSPITAL.

Mr. MAUNDER says that the indications are twofold, general and local. The general are, to improve the health by every means—change of air, liberal diet, and tonic medicines, cod-liver oil and the syrup of the iodide of iron being especial favourites. The local indications are, to prevent burrowing of pus and destruction of a large extent of skin, and consequent exhausting suppuration and ugly scarring. The abscesses should, therefore, be opened early with a fine knife; and, if the discharge be tolerably healthy, the walls of the cavities should be carefully kept in apposition by means of compresses and strapping around but not over the aperture. In this way reaccumulation of secretion is prevented, and healing by granulation is encouraged. Should the contents of the abscess be very unhealthy, the cavities should be stimulated to wholesome secretion for a few days by the injection of an iodine lotion—half an ounce of the compound tincture of iodine in eight ounces of water; and then compresses, as above explained, are to be used. Occasionally an exposed gland must be removed, either by enucleation or evulsion with the finger, or *potassa fusa* may be applied. Should the abscesses coalesce and degenerate into obstinate sinuses, they should be slit up; and the thinned skin on either side of the incision must often be cut away with scissors, to prevent the further formation of sinus. If this latter operation be resorted to, an open wound, almost level with the integumental surface, is formed, and, with care, can be induced to heal from its margins. Persons liable to swelling of the cervical glands should always keep the neck protected from currents of air. Mr. Maunder thinks that exposure of the neck to a variable temperature is a fruitful source of glandular swellings. Poptices should rarely be used.

In cases such as those which are ordinarily seen in hospital practice, Mr. JAMES E. ADAMS says that glandular abscesses in strumous subjects pursue most widely different courses in different subjects; and even the same patient may present them in various conditions at different times. Those which resemble in their course ordinary abscesses, by quickly attaining considerable size, and producing thinning and reddening of the skin, and being painful, require early and free incision; and, if the integuments be in the condition above mentioned, our knife-wound makes no worse a scar than the natural destruction of tissue would if the abscess were left. In other cases, we meet with considerable-sized collections of pus, commencing in the interior of glands, covered with thin but otherwise normal skin, very chronic and painless. In these, Mr. Adams has adopted the plan suggested by a recent writer, of emptying the cavity through a small puncture, and applying pressure. It often requires repetition, but in some cases produces a very favourable result as regards the scar. Those which are small in size, painless, thick-walled, and deeply seated, he generally leaves; and, under favourable conditions, they diminish in bulk, and occasionally disappear altogether. In all cases, he believes benefit is to be derived from the use of some one of the preparations of iron, cod-liver oil, and prolonged residence at the seaside; sea-air being almost an essential for those cases in which unhealthy sinuses or ulcers have followed the opening or breaking of the abscess.

## WESTMINSTER HOSPITAL.

The principle at which Mr. HOLTHOUSE always aims is to prevent a breach of surface, either by the spontaneous breaking of the abscesses or by the knife of the surgeon. The few cases which have come under his observation in hospital in-patients have been in connexion with extensive scrofulous ulceration of the skin consequent on the breaking of these abscesses; and his treatment has been directed to stop the further destruction of skin, to heal the ulceration, and to “disperse” such abscesses as may not already have broken. With this view, Mr. Holthouse usually prescribes from five to ten minims of the tincture of the perchloride of iron in half an ounce of water, with the same quantity (half an ounce) of cod-liver oil floating on it, three times a day; and the patient has the full diet of the hospital, with half a pint or a pint of porter daily, if not contraindicated. Unless the skin be much discoloured over the abscesses, he leaves them alone, and has often been gratified in

watching the gradual return of the skin to its natural hue, even in cases where at first sight it seemed almost beyond recovery; the final absorption of the contents of the abscess usually follows. If an abscess remain stationary, and it appear doubtful whether it will advance or recede, he poultices it with linseed-meal, which either acts as a discutient or hastens the progress of the matter towards the surface. If an abscess slowly enlarge in spite of treatment, and its eventual bursting seem certain, he opens it before the skin has become much discoloured, presses out the contents, and seals the wound hermetically; the fluid frequently re-collects, and requires again letting out; but with care there will be no loss of skin and scarcely an appreciable cicatrix. The ulceration which is left after much destruction of skin, Mr. Holthouse has seen rapidly heal under the iodide of lead ointment as a local application, and the internal exhibition of the remedies before pointed out.

The treatment of all scrofulous affections must be first of all constitutional. As it would be a mockery to prescribe good air, nutritious food, cleanliness, agreeable exercise, etc., to the class of patients who frequent our London hospitals, we must entirely fall back in their case on those therapeutical agents, half medicinal, half alimentary, that it is in our power to dispense—cod-liver oil and steel. Of cod-liver oil, Mr. THOMAS COOKE gives one ounce three times a day to an adult. Steel he gives, not in the astringent form of tincture of perchloride of iron, but in the very soluble and non-astringent forms of potassio-tartrate of iron, or citrate of iron and ammonia, which can be given in much higher doses without creating constipation. Fifteen grains of either of the above chalybeate salts, with fifteen minims of chloric ether to an ounce of water, form a most delicious mixture, which he gives the adults in ounce doses three times a day, with admirable results. Respecting local treatment, if he have to deal with a chronic abscess the integument covering which is still healthy, or with a more acute variety still in its incipient stage, he tries to avoid both the drain upon the system which is incurred by a suppurating sore, and the ugly cicatrix resulting therefrom. To this effect he covers the part with emplastrum ammoniaci cum hydragryo, which he renews every three or four days. This application, which is very similar to "emplâtre de Vigo cum mercurio", much used in France, he finds more effectual than iodine paint. If resorption do not take place, or if from the first the integument be thinned and livid, and the abscess on the point of bursting, he opens it largely, as much as possible in the direction of the folds of the neck. He then fills the cavity of the abscess, and covers the parts superficially with lint or tow dipped in a lotion composed of half methylated spirits and half water. He covers the whole with a piece of gutta-percha tissue, applies a bandage, and orders the dressing to be renewed morning and evening. He always obtains by this means a rapid union and a linear cicatrix.

#### CHARING CROSS HOSPITAL.

With regard to the treatment of scrofulous abscess of the glands of the neck, Mr. BELLAMY thinks that the first thing to be done is to endeavour to improve the patient's health by the administration of cod-liver oil and iron, either alone or combined with iodine, as in the syrup of iodide of iron, if there be considerable anæmia. The local application of iodine paint appears to be in these cases of very little use. When pus has formed, the abscesses should be opened by a free incision; and when they are indolent, stimulating injections of iodine, or zinc, or copper lotions are frequently of service. Sea-air and sea-bathing are as beneficial as anything.

Mr. FAIRLIE CLARKE points out that the first thing is to place the patient in favourable hygienic conditions—to see that he is well clothed, and that his diet is plain but nutritious, and taken at regular hours. The next thing is to prescribe those remedies which are of use in such cases, e.g., cod-liver oil or the syrup of the iodide of iron. As local applications it will probably be necessary "to ring the changes" upon various stimulating and antiseptic lotions, such as sulphurous acid or weak carbolic acid lotions. Mr. Fairlie Clarke has lately been trying a lotion composed of ten grains of common salt and five grains of nitrate of potass, added to a pint of water; and he finds that it acts as an excellent antiseptic, checking supuration, but promoting granulation and cicatrization. But, whatever lotion is used, it ought to be brought thoroughly into contact with the whole surface of the abscess. If the disease take the form of a sinus, the surgeon should bear in mind Mr. Hilton's admirable remarks in his lectures on *Pain and Rest*, and endeavour to give the part physiological and mechanical repose by studying its position, and, if need be, keeping it still by means of a pad and bandage. In this way, the surfaces will be most likely to unite, and there will be no strain upon the young and tender tissues.

#### THE HOSPITAL FOR SICK CHILDREN.

Mr. WARRINGTON HAWARD points out that, in considering the treatment of scrofulous glandular abscess of the neck, it is necessary to

remember that a great many of the cases of inflammation and abscess of the glands of the neck have nothing to do with scrofula, although the epithet "scrofulous" is frequently applied to them. The majority of such, among the poorer classes, are due to sores upon the head, which are often overlooked, or thought by the patient of secondary importance to the glandular swellings; and even among the upper classes, eczema and other eruptions on the scalp are a frequent cause. But when the affection is really scrofulous, and there is a general vulnerability of the lymphatic system, the inflammation is slow, though pertinacious, and the result is more often a caseous degeneration of the cells of the alveoli of the gland than the formation of ordinary pus. When, however, the latter forms, or the caseous material softens and liquefies, a very small puncture should be made in the skin, and the contents of the abscess gently squeezed out, pressure being made by a pad of lint on each side of the opening. The puncture may require to be occasionally reopened with a probe; but by this means, adopted early, the integrity of the skin is preserved, and the unsightly scars and puckerings often seen in such cases are prevented. The health should be at the same time improved by cod-liver oil, iron, and sea-bathing, the general treatment being quite as important as the local. While the glands are only swollen and tender, and before supuration has taken place, they should be left alone, or merely covered with cotton wool. Mr. Haward has no doubt that poulticing and painting with iodine only do harm.

#### ABERDEEN ROYAL INFIRMARY.

In treating scrofulous abscess of the glands of the neck, Dr. A. OGSTON has lately obtained most satisfactory results from repeatedly drawing off the pus by small cannule. As soon as fluctuation is evident, a minute trocar is introduced, and the abscess is emptied as completely as possible through the cannula. The cannula is then withdrawn, and the wound heals at once. This proceeding is repeated as soon as the matter has re-collected; the abscess is again emptied, and every time it refills the same steps are had recourse to, before the fluid collects to such an extent as to cause tension. It has usually to be repeated many times, but eventually the fluid becomes rather watery than purulent, and at length ceases to be formed. Abscesses treated in this way can be readily cured without scar or deformity; and, even when their site is very superficial, and they burst during the treatment, the small opening they give rise to heals without a scar—a temporary discoloration of the skin remaining for a few months, and then entirely vanishing. When such a superficial abscess threatens to point, Dr. Ogston is in the habit of opening it with a minute lance-shaped needle, about one millimètre in breadth. The pus is squeezed out, and the little wound heals by first intention. He finds that the treatment by collodion invariably fails. In cases of open scrofulous glandular sores of the neck, with undermined edges or hypergranulation, he finds cauterisation with potassa fusa furnish the best results—the elevated white scar produced being a smaller deformity than the depressed natural cicatrix or the scars of other escharotics.

#### GLASGOW ROYAL INFIRMARY.

Dr. MORTON follows the following method of treatment. When all attempts to prevent supuration have failed, and when it is fully established, it is his practice to open the abscess thoroughly with the knife, in such a direction that the natural folds of the skin may cover or obscure the slight scar left, preferring, when it corresponds with this, the long diameter of the abscess. He then uses a tent of lint dipped in camphorated oil, and covers the part with an oil- or water-dressing. The use of the tent is not continued after the first or second dressing. This plan promotes rapid healing, with less scar than we usually see. Such is Dr. Morton's experience in both hospital and private practice. He has used the liquor epispasticus of the *Pharmacopœia*, applied by a camel's hair-pencil to the interior of the abscess; but he never uses caustics. The latter, in Dr. Morton's opinion, tend to increase the size of the scar or cicatrix; and in several instances, chiefly in private practice, he has excised a dark stain, produced by the use of nitrate of silver, and with the most satisfactory results. Probably excision of unsightly scars might be more frequently performed, and with benefit, upon the necks of fair patients.

#### GREAT NORTHERN HOSPITAL.

##### AMPUTATION AT THE HIP-JOINT.

AMPUTATION at the hip was performed by Mr. Carr Jackson at this hospital, on December 13th, on a man aged 20. The patient appears likely to do well. The case is one of interest, and we shall report it at greater length. Mr. Jackson had, many months previously, excised the head of the femur, but augured unfavourably of the result, on

account of the soft and diseased state of the bone at the point of section; and so sinus after sinus formed, and the only alternative lay in removing the limb. The large surface of the wound was washed over with pure sulphurous acid, and the resulting suppuration has been very slight.

## BRITISH MEDICAL JOURNAL.

SATURDAY, DECEMBER 30TH, 1871.

THE following appeared in our second edition last week, and in 4000 copies of our first edition.

Friday, 8 P.M.

The character of the symptoms attending the convalescence of His Royal Highness the Prince of Wales was, up till yesterday afternoon, such as to warrant the best founded and most sanguine anticipations. At that time we were able to state that "the defervescence is complete; there are no visceral troubles, and the Prince is regaining strength". During the night, however, and in the course of to-day, it was stated in a Windsor telegram that there was an increase of fever, and that there was great anxiety as to the Prince's condition. From inquiries which we have made in the most authentic quarters, we are glad to learn that the report is unfounded—that the Prince at a late hour this (Friday) evening was better than hitherto, and that there is no increase of fever. The convalescence from typhoid fever is always a process of tedious character and never without anxiety; and we can but express our great satisfaction—which we feel sure will be universally shared—that the Prince is continuing to do well, and that his symptoms still give promise of a happy and uncomplicated recovery.

### THE HEALTH OF THE PRINCE OF WALES.

THE sequelæ of typhoid fever are numerous, and it is comparatively rare that a patient who has passed through a severe attack of the fever altogether escapes some kind of local trouble after emerging from the fever. These are not, of course, essential characters of the fever, or connected with its process; from all grave complications of that kind the Prince has happily escaped, and he is passing through the stage of convalescence under favourable general conditions. As he has providentially escaped all organic visceral lesion, we need not conjure up the long list of ills which sometimes impede recovery after typhoid fever. That which is now a source of trouble to the Prince belongs to the class of local and superficial sequelæ of the fever, which in the experience of surgeons are very common—more common, perhaps, than even experienced physicians suspect, or than some of the best textbooks would lead us to suppose. At the close of last week, the Prince began to suffer from a somewhat variable, but at intervals a very severe, pain over the upper edge of the hip-bone—the posterior part of the crest of the ilium. Such tenderness might, it was then thought, arise from the pressure of long recumbency—although, thanks to careful nursing, there has been a remarkable absence of trouble on this score, and there has not been any bed-sore—or it might be due to a local periostitis, or the inflammation precursory to the formation of a superficial abscess. On Sunday, Sir James Paget was in attendance at Sandringham. There was not then any proof of more than the local tenderness, which might well be merely indicative of pressure and local nerve disorder. The pain, however, has persisted, and the symptoms are now indicative of a local inflammation of the structures over part of the hip-bone, such as is not uncommon after typhoid fever. With this there has been an access of

feverishness and some disturbance of rest, such as this local trouble readily explains. Sir James Paget has been called again to Sandringham to enter into the counsels of the Prince's physicians, and it is probable that his stay will be prolonged for some days. There is nothing in the Prince's condition to create alarm.

### SHOULD HOSPITALS TAKE PAYMENT?

AT the present time, when our Association is doing much, and successfully, to introduce reforms and to impress the public mind with the necessity of remedying abuses in the out-patient department of hospitals, it is well that every fact should be weighed, that every claim should be considered, and that we should make up our minds fully not only as to the class which it is our desire to relieve, but also as to the principles upon which admission should be granted.

The main abuse which is at present complained of, is that many persons resort to our hospitals who are well able to pay something for medical advice. Those who are above the level of charity are doing an injustice to themselves and to medical practitioners, by suffering themselves to join the great and growing mass of charity-seekers. Now there is at some few hospitals a system which may be thought in some degree to remedy this abuse; and it is this to which we desire to-day to draw the attention of our readers. By the system to which we allude, the patient contributes something to the funds of the hospital, and thus it is supposed that he no longer abuses the charity. At some hospitals admission may be obtained by shilling or half-crown tickets, which are available for a month or more; at others a weekly payment is exacted for medicines; at others, again, a body of workmen club together and constitute themselves governors of the hospital. These are some of the ways in which it is sought to make the applicants pay something for their medical treatment. But are these plans wise or just? Is it wise that the hospital should thus undertake to sell advice and medicine? Is it just towards the profession that any section of the public should be taught to believe that they can purchase skilled treatment by the payment of half-a-crown, which, according to Dr. Guy's statistics, is just about what the medicine alone costs per case?

The view of the free hospital or dispensary to which we incline is, that it should be purely charitable; that it should take nothing from those whom it relieves; but that its relief should be restricted to such persons as are fit objects for charity. We take it for granted that, if an applicant be in a position to be able to pay a general practitioner, he will be rejected altogether; but if, on the other hand, he can only afford a small payment, still such payment ought to be made to a medical man through the provident dispensary or sick club. The money which is expended on the purchase of tickets is not given from charitable motives, but is paid for value received, and that value consists chiefly in professional advice, the cost of the medicines being comparatively insignificant. When such money is added to the general income of the hospital, we may fairly consider that it is taken out of the pockets of medical men, and that, so far, an injustice is done to our profession. If a hospital see sufficient reason for making provision for a grade of patients who are above the level of charity, it ought to be done by the formation of a provident department, as at Devonport. Perhaps it is more desirable that the provident dispensary should be affiliated to the hospital, than that it should form an integral part of the charity. It is thus most likely to become ultimately self-supporting. But in either case the principle followed out is the same—i.e., a large number of persons form themselves into a sort of mutual assurance society, and, by small but regular payments, make provision against a time of sickness: and inasmuch as their payments are made on a commercial footing, and not from any motives of charity, the money subscribed, after deducting 20 or 25 per cent for drugs and working expenses, is divided among the medical men with whom the contract is formed.

It would appear, therefore, that the system of admission to hospitals by payment is open to various objections. In the first place, persons of the middle class, who could well afford to pay the small fees of a

local practitioner, think that they are perfectly justified in availing themselves of the hospital. In proof of this, we may mention that we have repeatedly known persons to travel long distances and incur heavy expenses, and then, instead of consulting a physician or surgeon privately, take advantage of these shilling tickets to obtain first-class advice. Secondly, the scale of professional remuneration is lowered; for, if the applicant have obtained for a shilling a month's skilled attendance and medicine, it is not very probable that he will afterwards be content to pay a general practitioner even five shillings a visit. It thus becomes evident that money so paid to the hospital is in reality subtracted from the income of medical men; added to which we may say that, though advice thus obtained is not entirely gratuitous, and therefore does not tend directly to pauperise the middle classes, yet it cannot fail to diminish their independence, as it leads them to expect money's worth for less than money's value, while it does not foster those habits of forethought and self-reliance which it is so desirable to encourage. We call attention to the proposed further action of the Metropolitan Counties Branch upon this whole subject, to which we invite the most earnest attention of the profession.

#### CERTIFICATION OF MIDWIVES.

THE attention of the Council of the Obstetrical Society has been directed to the extreme ignorance prevalent amongst women who practise as midwives, and a committee of the Council has had the subject under prolonged consideration. The result has been a report to the Council, recommending the establishment of a Board of Examiners, for the purpose of examining such women as may choose to present themselves, and granting to them a certificate of competency to attend natural labours. The scheme is embodied in the proposed additions to the Bye-laws and Regulations. The Council recommend it for adoption, feeling sure that it will prove a boon both to patients and to practitioners, since it is only the ignorant and uninstructed midwife who is rash enough to undertake the sole charge of cases in which the advice and assistance of the regularly qualified practitioner ought to be sought. We entirely concur in this course, which is, indeed, the fulfilment of a suggestion which we have repeatedly made, and which has been urged from other sources. We have reason to know that the Government would not be averse to giving official sanction to some such scheme, if this were thought desirable; but a tentative process may be most advisable in the first instance.

*Plan for the Examination of Midwives recommended by the Council for the adoption of the Society.*

#### BYE-LAWS—CHAPTER XVI.

I. That an Examining Board be formed, consisting of six members; viz., a chairman, three ordinary members, and the honorary secretaries (*ex officio*). (The two non-official members of the Board longest in office to retire annually.) [The Council recommend the following gentlemen to form the first Examining Board: Dr. J. Hall Davis, chairman; Dr. Aveling, Dr. Meadows, Dr. Leonard Sedgwick, and the Honorary Secretaries.] II. That Examinations be held at the Society's Library, on the second Wednesdays of the months of January, April, July, and October, at eight o'clock P.M., or at such times as the Board of Examiners may from time to time determine. III. That candidates for the admission to the Examination be required to submit to the Honorary Secretaries of the Society certificates of the following qualifications at least fourteen days before the date of the Examination:—(a) A certificate of moral character. (b) A certificate showing that the candidate is not under twenty-one years of age, and not over thirty years of age; but that up to the year 1877, candidates above thirty years of age be admitted to Examination under special circumstances satisfactory to the Board of Examiners. (c) Proof of having attended the practice of a lying-in hospital or charity for a period of not less than six months; or of having personally attended not less than twenty-five labours under supervision satisfactory to the Board of Examiners. (d) Proof of having attended a course of theoretical teaching by lectures or tutorial instruction, the details of which must be submitted to, and receive the approval of, the Board of Examiners. IV. That the candidates be required to pass: (1) a written examination; (2) an oral and practical examination upon the following subjects: (a)

the elementary anatomy of the female pelvis and generative organs; (b) the symptoms, mechanism, course, and management of natural labour; (c) the indications of abnormal labour, and the emergencies which may occur in practice; (d) a general knowledge of the puerperal state; (e) the management of new-born children and infants; (f) the conditions as to air, food, cleanliness, etc., necessary for health; (g) the duties of the midwife with regard to the patient, and with regard to the seeking of medical advice. V. That, on satisfying the Board of Examiners as to her qualifications, the midwife should receive a diploma certifying that she is a skilled midwife, competent to attend natural labours. VI. That the fee for this diploma be one guinea; and that unsuccessful candidates be required to pay a fee of five shillings.

DR. ROBERT BEALES, Congleton, has been appointed a magistrate for the county of Chester.

It is proposed to erect a Dispensary and Hospital at Berwick, and a piece of ground is to be purchased for a site.

A DETAILED and important series of instructions to vaccination officers, signed by Mr. Simon, have been issued by the Local Government Board.

SIR HENRY HOLLAND has seen many men and many countries—the men and the countries best worth seeing in his time; and his *Recollections of Past Life*, which issues this week from the press, will be found of very great interest.

MR. CORRANCE, M.P., read an interesting paper before the Farmers' Club at Framlingham last week, on Poor Relief, Medical and General. We shall probably be able to notice it at greater length on a subsequent occasion.

THE number of cases of small-pox in the Vienna hospitals was on the increase on the 22nd instant. During the previous week, seventy-four cases had been admitted. From the 12th to the 22nd, there were twenty-five deaths from small-pox.

#### THE FIRE IN CHICAGO.

DR. GUSTAV SIMON, Professor of Surgery in Heidelberg, and Dr. O. Becker, Professor of Ophthalmology, have issued an address to the medical profession in Germany, soliciting aid in behalf of a hundred and twenty-five medical practitioners in Chicago, whose property was destroyed by the fire in that city. They have been informed by their correspondent in Chicago, that money is of less importance than books and instruments; and they solicit contributions of these.

#### NEW MEDICAL COLLEGE FOR WOMEN.

A MEDICAL College, subject to the supervision of the University of New York, has been opened in that city. The College is, it is stated, designed to give a "perfect medical education without expense to the recipient"; but, as the term of study is apparently limited to thirty-two weeks, much cannot be said of the movement.

#### PROSECUTION UNDER THE MEDICAL ACT.

AT Shrewsbury, on December 21st, Thomas Andrews, of that town, was charged, at the instance of the Shropshire Ethical Branch of the British Medical Association, with an infringement of the Medical Act, by falsely assuming the title of M.D. It was proved that the defendant, who had been for some years a druggist in the town, had recently sent out a bill for professional attendance, had attached M.D. to his name, and had M.D. painted underneath his name on a lamp in front of his door. For the defence, it was shown that he had received a diploma of the Medical University of Pennsylvania—a discreditable establishment, whose scandalous sale of diplomas has recently been fully exposed in the American papers, as stated in the *BRITISH MEDICAL JOURNAL* a few weeks ago; and Mr. Motteram, barrister, who appeared for the defence, contended that, even if the College had no power to grant the diploma, if the defendant believed that it had the charge must fall to the ground. He called Mr. George Lever to swear to the

authority of the diploma, which he did. Being asked to read it (it was in Latin), the witness declined to do so, and subsequently said that the knowledge of Greek and Latin was looked upon as a secondary consideration in the Medical University alluded to. He visited the University, and attended lectures; but he believed diplomas, after an examination by a duly authorised board in this country, were granted. He had no idea, however, what the nature of the examination was. The farce enacted, of a supposed examination, has already been fully exposed in the papers of Philadelphia, New York, and Boston. The bench fined the defendant £20, but granted a case for the superior courts.

#### TYPHOID IN NEW DISTRICTS.

THE *South London Courier* says: "If report be correct, the drainage system of South London is far from perfect, and this being so, the lengthened reign of typhoid and other fever in the district is not to be wondered at. We are in a position to state that a very large number of new buildings, even in the principal thoroughfares, are not connected with the street sewer. A heavy responsibility rests upon those who let houses with a knowledge of this state of things, and it behoves all persons taking newly-built houses to look to their drains."

#### DIAGNOSIS FROM AFAR.

AN amusing and highly ingenious diagnosis has been made of the Prince's illness by some of the Berlin physicians. They have, by some reasoning not very evident, come to entertain the idea that the outbreak at Londesborough Lodge was not one of typhoid, but of trichinosis—a disease which has been very prevalent in some districts of Prussia for the past few years. The character of the outbreak at Scarborough, the slow abatement of the temperature, and the bronchial affection in the Prince's illness, afforded perhaps *à priori* grounds for the strange opinion of the Berlin physicians; but it need not be said that trichinosis neither produces the specific spots, nor does it present the typical variations of the temperature of typhoid fever, which were so well marked in His Royal Highness' illness.

#### PROFESSIONAL ETIQUETTE.

A GOOD deal of discussion has naturally been raised in professional circles by the publication in the *Times* of a sort of *communiqué* from Sandringham, paying a very glowing and earnest tribute to the devotion and personal services of Dr. Gull to the Prince of Wales. This paragraph was gracefully and even elegantly worded, and expressed no doubt with accuracy the feelings of those for whom it spoke. On the other hand, it was so couched as to run counter to the most valued traditions of the profession, which prescribe the utmost modesty and reserve in the discussion of personal medical services in public prints, and is justly jealous of the effusive expression in such places of the verbal thanks of grateful friends, for which there are other acceptable modes of recognition. In the ordinary spheres of life, such grateful expressions of personal feeling occasionally find their way into the papers, almost invariably to the annoyance of the medical man who is the object of them. They are always observed with regret, and have so frequently been visited with censure by the medical profession and the medical press, that every medical man of any position is nervously anxious to avoid them, and that the effect, of general discouragement has been to repress them, with rare exceptions: and this is well for the dignity of the profession and well for the public interests, which are best safeguarded by a delicate observance of such admirable professional traditions. It would be highly inconvenient if the metropolitan and provincial press were flooded with encomiums on the personal character, skill, and services of medical men, conveying the estimate formed at the time by their grateful patients, and the families of those patients. This would not be the best means of arriving at the knowledge of modest worth, or the truest gauge of professional merit. The precedent, therefore, thus set is not one to be followed. It must, undoubtedly, have caused somewhat mixed emotions of obligation and annoyance to the physician whose private services it recog-

nised. And while, under the surrounding circumstances, silence was the course which probably best became him, in the confidence that his personal character and position could not leave any misapprehension, it is none the less, perhaps rather the more, our duty to indicate the objections to what has occurred, and the necessity of permitting no relaxation in the strictness of a rule of public modesty which is important to the character of our profession and to the public interests.

#### A DISGRACEFUL PROCEEDING.

WE have before us some particulars of a disgraceful and disgusting affair at Bridgewater. A baker was convicted of selling bread from his shop; his son, who was employed in making the bread, being actually at the time suffering from small-pox, and covered with the pustules. The disgusting and wicked offence was proved, and a fine of £10 was inflicted. But we find that at a meeting of the Bridgewater Guardians shortly afterwards, this same man had the effrontery to tender to supply the workhouse-bread; and that, notwithstanding the protest of a minority, his tender was accepted; Mr. J. R. Smith stating in defence of the baker, "that he had the misfortune, and in his ignorance, to allow certain things to be done; but his was not the only case of the kind. He knew of a small shop in the town where precisely the same thing had been done, but, unfortunately, it was discovered too late to proceed against the offender". It is almost surprising that this man was not also sought out to give him a share in the contract. Owing to the long-standing neglect of vaccination by the Guardians, Bridgewater has suffered fearfully this year from small-pox. This last act is an outrage upon decency, and in contempt of the respect due to the law.

#### CLUB-FEES.

THE following document has been favourably received by the medical practitioners of Norwich. We should be glad that so good a precedent should become universal.

"We, the undersigned, medical practitioners residing in Norwich, fully endorse the following resolutions, and pledge ourselves heartily to co-operate with our medical brethren in carrying out the same:—That the payment for attendance and medicine by each member of a benefit society be not less than four shillings *per annum*; that midwifery, vaccination, and dentistry, be considered extras; that no member residing more than three miles from his club-house be entitled to attendance at his own residence; that no contracts be entered into for attendance on the wives and families of members of clubs in which such an arrangement does not already exist; that the fee for attendance on the wives of members of clubs in their confinements be not less than one guinea; that the fee for examination of candidates for admission and re-admission to benefit societies, and for all certificates (except the ordinary certificate of ability or inability to work), be one shilling; that the fee for a certificate of death for a burial club be two shillings and sixpence.—Sturley Payne, John Crook, R. Cremer, A. M. F. Morgan, Robert Thompson, J. B. Pitt, F. C. Bailey, John Brownfield, Wm. Summerhayes, Michael Beverley, M.D., Phineas Pitts Langford, John F. Watson, Wm. Guy, M.D., Joseph Allen, Henry Ward, David Penrice, Charles Williams, Thos. W. Crosse, R. E. Gibson, Charles Evans Muriel, Haynes Robinson, Alfred Master, William H. Day, William Woodhouse, W. Cadge, R. Septimus Davenhill, Frederick Sutton, W. Bransby Francis."

#### COUNTER-PRACTICE.

A CASE of quackery, which resulted in the death of a little boy three years old, was investigated by Mr. Richards, the deputy coroner for East Middlesex, a few days ago. The child's mother gave the following evidence. "The deceased was taken ill on Monday last with a severe fit of coughing and choking, and I took him to the 'hall,' in Goldsmith's Row. I was there told that he was suffering from whooping-cough, and I obtained from the doctor there a bottle of physic to induce vomiting, for which I paid. They painted the deceased on the chest, throat, and back, and I took him home and gave him some of the medicine, but he was not at all sick. On Tuesday he ate his dinner, but appeared sleepy afterwards, and at six o'clock that evening was seized with a fit of choking. My husband took him to Dr. Bryant,

but he died ten minutes after that gentleman saw him. The people in Goldsmith's Row promised to give me a certificate to enable me to bury the deceased, but somehow it was stopped, although it had been written out." Dr. Bryant said that the child presented no sign of whooping-cough. He died from croup, and if any proper medical man had been called in he had not the least doubt that the child would have been alive. The coroner, referring to these observations, said:—"The extent to which chemists infringe the provisions of the Act is something frightful, having regard to the fact that the lives of many persons are annually sacrificed through the ignorance of these unqualified medical practitioners. The consequence is that at the last moment a real doctor is called in, and he refuses to certify, the result being a coroner's inquiry and the waste of the county money. The want of a public prosecutor is here most manifest; but until this crying evil becomes thoroughly exposed through the medium of the public press, we may look in vain for any proper measures being taken to check the frauds which are daily perpetrated upon the true medical profession by men who know as much of the human anatomy as my inkstand."

#### HARVEIAN SOCIETY OF LONDON.

THE following are the officers and Council proposed for 1872:—*President*: C. Handfield Jones, M.B., F.R.S. *Vice-President*: M. Berkeley Hill, Esq.; W. Hickman, M.B.; J. B. Curgenvin, Esq.; W. H. Broadbent, M.D. *Treasurer*: H. W. Fuller, M.D. *Secretaries*: H. C. Lawrence, Esq.; G. Eastes, M.B. *Council*: J. Hall Davis, M.D.; T. Carr Jackson, Esq.; T. Morton, M.D.; A. H. Nowell, Esq.; W. B. Owen, Esq.; E. E. Sass, Esq.; J. G. Westmacott, M.D.; F. B. White, Esq.; G. Benson Baker, Esq.; Thomas Raynor, Esq.; Thomas Thorman, Esq.; E. Parker Young, Esq. The election will take place at the Society's rooms, on Thursday, January 4th, 1872:

#### PRIZES OF THE ROYAL COLLEGE OF SURGEONS.

FOR the Jacksonian Prize on the Treatment of Wounds after Operations, essays on which were to be sent in before Christmas-day last, the unusual number of six have been received. The essays for the Collegial Triennial Prize on the Structure and Functions of the Medulla Oblongata, including the connexions of the Central Nerve-Roots, must be sent in before Christmas-day 1873.

#### PATHOLOGICAL SOCIETY OF LONDON.

THE following are the officers and council proposed for election for 1872, at the annual meeting to be held on January 2nd:—*President*: J. Hilton, Esq. F.R.S. *Vice-Presidents*: E. Crisp, M.D.; W. H. Dickinson, M.D.; R. Quain, M.D.; S. Wilks, M.D.; J. Cooper Forster, Esq.; John Gay, Esq.; Jonathan Hutchinson, Esq.; John Wood, Esq., F.R.S. *Treasurer*: C. Murchison, M.D., F.R.S. *Honorary Secretaries*: W. Cayley, M.D.; J. W. Hulke, Esq., F.R.S. *Council*: W. H. Broadbent, M.D.; W. Cholmeley, M.D.; W. S. Church, M.D.; J. Langdon H. Down, M.D.; A. B. Duffin, M.D.; C. H. Fagge, M.D.; T. H. Green, M.D.; J. H. Jackson, M.D.; R. Martin, M.D.; C. R. Nicoll, M.D.; F. W. Pavy, M.D., F.R.S.; F. Robinson, M.D.; H. Arnott, Esq.; T. J. Ashton, Esq.; J. Couper, Esq.; J. Croft, Esq.; E. D. Hacon, Esq.; A. B. R. Myers, Esq.; W. Potts, Esq.; W. Squire, Esq.

#### THE NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

WE have received a copy of the *Transactions* of this Society, which are to be issued monthly, and will contain reports of the papers read and pathological specimens shewn at the meetings of the Society, with the discussions thereon. The contents of the first number augur well for the future success of the undertaking. They consist of a report on pathological specimens and three papers—one, by Mr. H. E. Armstrong, on a case of Corymbo-Crystalline Small-pox in a person not Vaccinated; a case of Faecal Accumulation, by Dr. C. J. Gibb; and Observations on Albinism, by Mr. Christopher Jeaffreson.

## SCOTLAND.

SMALL-POX is on the increase in some of the more northern towns of Scotland. In Edinburgh, however, it is rather on the decrease.

#### THE GLASGOW OPHTHALMIC INSTITUTION.

AN account of this institution, which was originated by Dr. Wolfe three years ago, appears in a recent number of the *Glasgow Daily Herald*. The premises which were opened by the directors in 1870 have now become too limited; and a fresh appeal is to be made to the public for subscriptions to enable them to build or buy a house of much larger dimensions.

#### THE EDINBURGH UNIVERSITY ENDOWMENT ASSOCIATION.

AT the annual general meeting of this Association, held on the 20th instant, it was intimated that the Syme Fellowship had been placed on a permanent foundation. The following motion, proposed by Lord Neaves and seconded by Professor Sir Robert Christison, was adopted unanimously:—"That the Association views with great satisfaction the completion of the Syme Surgical Fellowship; that it congratulates the University on the acquisition of so valuable and appropriate a memorial of one of its greatest teachers; and again expresses its thanks to Dr. Charles Murchison, and the Committees in London and elsewhere, for their earnest and successful endeavours to found and endow the Fellowship."

#### THE GLASGOW MATERNITY HOSPITAL.

THE House Committee of the Directors of the Maternity Hospital have drawn up a statement, which has been forwarded to us, containing the results of an investigation into the case of the woman who was delivered outside the hospital, and whose case we last week noticed. It is affirmed by the Committee, that the woman was delivered before any application was made for admission at the hospital, and that all the requests made on the woman's behalf were immediately granted. They defend entirely the conduct of the nurse and matron. Some of the statements of the Committee are, perhaps, somewhat feebly apologetic.

#### THE MEDICAL POLICEMAN.

THE authorities of the counties of Haddington and Berwick have adopted a system of sanitary inspection to be carried out by the police, who are to keep a record of all cases of infectious disease, act as inspectors of nuisances, and generally superintend the sanitary condition of the various districts. Such a system may be cheap and satisfactory to the parochial boards; but, although the police may, under some circumstances, make good health-inspectors, there is at the same time a charming absurdity in the idea of the police-constable undertaking the sanitary control of his district and many other duties which should properly devolve on a medical officer of health.

THE EDINBURGH UNIVERSITY COURT AND THE LADY-STUDENTS. THE University Court has already met on two occasions, during the past ten days, to consider the lady-student question. The first meeting took place on the 21st instant. The object of the meeting was to hear an appeal by Professors Masson, Bennett, and Calderwood, against the following resolution of the Senatus Academicus.

"The Senatus Academicus represent to the University Court the propriety of rescinding their regulations with reference to the admission of women to medical education in the University, but without prejudice to the rights and interests of those ladies who have already entered upon a course of study, and without prejudice to the rights of professors to give separate instruction to ladies in such classes as the University Court may from time to time think fit and approve."

The majority of the Senatus who carried the resolution were represented by Professors Muirhead, Turner, and Lister. This resolution, Professor Masson stated, had been carried, in consequence

of the absence of certain members of the Senatus, by a majority of fourteen to thirteen; but out of the thirty-six professors composing the Senatus, eighteen had since signed the protest now presented by him against the resolution. Moreover, two of the remaining eighteen, he believed, would not declare themselves on either side. He presented the further legal opinion of the Lord Advocate and Sheriff Fraser as to whether, in the first constitution or charter of the University, or in any of the subsequent statutes, there is anything which limits the benefits of the University to male students. It was to the effect that the University Court, by Sec. 12 (2), are now vested with all the powers of internal management and regulation formerly possessed by the magistrates and Council; they have done what the latter never did, although they lawfully might. They have, by their resolution of November 1869, given to women the right to demand, equally with male students, admission to the University. At the same time a letter from Miss Louisa Stevenson was submitted, with lists of the Executive, the Edinburgh, and General Committees for Securing a Complete Medical Education to Women. The list contained 943 names. The Court adjourned until Tuesday, when the matter was again considered; but they arrived at no resolution. The Court meets again on Tuesday. We understand that the following plans have been suggested to enable lady-students to obtain a medical education at the University: 1. That the ladies should be admitted to the ordinary classes; 2. That the medical professors should be required to deliver to them separate courses of lectures; 3. That special lecturers should be appointed by the University to teach them in separate classes; 4. That the ladies should be allowed to obtain instruction from any recognised extramural teacher, and subsequently admitted to the ordinary examination for the University degree. Thus there are many alternative measures offered to the University Court, by which they might meet the demands of the ladies for medical education, without incurring the objections and inconveniences attaching to mixed classes.

### THE CONTAGIOUS DISEASES ACTS.

THE following memorial has been addressed to the Right Hon. H. A. Bruce, M.P., Secretary of State for the Home Department, signed by the Presidents of the London Colleges, the medical officers of the Royal family, and a number of the most distinguished members of the profession.

Sir,—We, the undersigned, beg to express to you the deep and continued interest we feel in the subject of legislation for the diminution of venereal disease.

Firmly convinced as we are, of the deteriorating influence exercised by this form of disease on the public health, and painfully familiar with the serious suffering which it entails on large numbers of innocent individuals, we are most anxious that, in any forthcoming measure, nothing should be done to weaken the beneficial sanitary operation of the Acts at present in force, which can be shown to have reduced the more serious form of disease by considerably more than one-half in the districts where they are in operation. (See the evidence of Dr. Balfour before the Royal Commission.)

We especially wish to protest against the erroneous supposition that a personal examination is deemed by the women themselves either so degrading or repulsive as has been represented. We know, by long experience of this class, that they will flock in crowds to our public hospitals for admission, although the presence of a number of medical students renders the exposure far greater than in the private chambers of an institution appropriated for this purpose by the Acts.

There is no difficulty in obtaining their voluntary attendance for even public examination when sick and incapable of further struggle with disease; but we know that, with rare exceptions, they cannot be induced to submit themselves for treatment in the earlier and less painful stages of their complaints, when, for obvious reasons, they are most actively instrumental in communicating infection.

We therefore believe it to be absolutely essential to the success of any Act of the legislature on this subject, that it should provide effectually for the earliest possible detection and treatment of disease in public women; and we are unable to see how this can be accomplished otherwise than by a system of periodical examinations.

If then, sir, we are warranted by recorded facts in our belief that the temporary seclusion of these diseased women in a more healthy moral atmosphere has been found to contribute in no unimportant proportion of them to their restitution to the paths of virtue; if, both physically and morally, they have been thereby raised in the scale of humanity, we trust you will not listen to a factious opposition, founded on a most imperfect knowledge of the character and altered nature of these women, and of the extent of the evils to be remedied.

We conclude, sir, with the expression of a most earnest hope that, in any future legislation on this subject, the main principles of the Acts of 1866 and 1869 may remain unaltered.

We have the honour to be, sir, your obedient servants.

To this the following reply has been received.

Whitehall, December 21st, 1871.

Sir,—I am directed by Mr. Secretary Bruce to acknowledge the receipt of your letter of the 18th instant, with accompanying memorial from the leading members of the medical profession on the subject of legislation for the diminution of contagious diseases; and I am to inform you that the statements contained in the memorial will be weighed by Her Majesty's Government with the care due to the opinions of men of their professional eminence, in their bearing on the important and difficult subject to which they relate.

I am, sir, your obedient servant,

(Signed)

A. F. O. LIDDELL.

To H. Spencer Smith, Esq., 9, Queen Anne Street, W.

### EPIDEMICS AT WEST NEWTON.

IN reply to a communication which we addressed to him on this subject, Mr. A. E. Barrett of Grimston has been good enough to draw up for us the following memorandum concerning recent epidemics at West Newton, the home village of the Sandringham estate.

Scarlet fever commenced at the beginning of August, and has continued to the present time. Almost the whole village has suffered. There have been five deaths from scarlatina maligna.

It is perhaps worthy of remark, and may throw some light on the causes of diphtheria and scarlet fever, that when diphtheria occurred here in 1868, the exudation-membrane was so constantly absent, that I and those who were assisting me in my practice gave it the name of the "Sandringham sore-throat", to distinguish it from ordinary diphtheria; and that it was most fatal at the higher parts of the village.

At the same time, at an elevated spot called Harpley Dams, nearly four miles east in a straight line from West Newton, and similarly exposed to northerly winds, a precisely similar sore-throat appeared, and was equally fatal. The cases occurred in a cottage belonging to the Earl of Leicester, well built, roomy, and apparently free from all possibility of contagious or malarious influences. Only four cottages stand on this hill, and they are semidetached, and, though new, have stood at least eleven years; they obtain their water from a deep well in the chalk.

When scarlatina maligna appeared in West Newton this year, it appeared almost at the same time on this isolated hill, and proved fatal to two strong farm lads, and attacked severely three or four other persons.

With regard to the typhoid in West Newton, it may be observed that the first epidemic commenced in September 1860, after a most remarkably wet summer; that the first cases began at a position below the churchyard; and that, the soil of the place being of a very porous nature, and the decaying humanity being only separated from the upper water-bearing stratum by five or six feet, there is a possibility of the whole water-supply being polluted from that source.

In 1860, typhoid fever attacked two families containing respectively 10 and 9 members. In the first, there were 10 cases and 1 death; in the second, 5 cases and 1 death. In 1870-71 the disease prevailed in three families. In one, each of the ten members of which it consisted was attacked, and two died; in the second (8 members) there were 4 cases with 2 deaths; in the third (2 members) there was one case, which died.

# BRITISH MEDICAL ASSOCIATION.

## OFFICERS AND COUNCIL FOR 1871-72.

**President**—JOHN WHIPPLE, F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

**President-Elect**—ALFRED BAKER, F.R.C.S., Surgeon to the General Hospital, Birmingham.

### Permanent Vice-Presidents.

JAMES HEYGATE, M.D., F.R.S., Derby.  
GEORGE S. JENKS, M.D., F.R.C.P., Bath.  
JAMES R. W. VOSE, M.D., F.R.C.P., Liverpool.  
C. RADCLYFFE HALL, M.D., F.R.C.P., Torquay.  
ALFRED LOCHÉE, M.D., F.R.C.P., Canterbury.

GEORGE BURROWS, M.D., F.R.C.P., F.R.S., London.  
EDWARD WATERS, M.D., F.R.C.P., Chester.  
CHARLES CHADWICK, M.D., D.C.L., F.R.C.P., Leeds.  
FRANCIS SIBSON, M.D., D.C.L., F.R.S., London.  
EDWARD CHARLTON, M.D., D.C.L., Newcastle-on-Tyne.

**President of the Council**—WILLIAM D. HUSBAND, F.R.C.S., Surgeon to the County Hospital, York.

**Treasurer**—RANDLE WILBRAHAM FALCONER, M.D., F.R.C.P., D.C.L., Bath.

**General Secretary**—(for 1871) T. WATKIN WILLIAMS, F.R.C.S., Birmingham; (for 1872) FRANCIS FOWKE, Esq., 37, Great Queen Street, London, W.C.

**Editor of the British Medical Journal**—ERNEST HART, Esq., London.

## THE MEDICAL INSTITUTIONS AND PREVAILING DISEASES OF VICTORIA.

[FROM A SPECIAL CORRESPONDENT.]

## III.

THE GEELONG HOSPITAL is also a two storied building on the corridor system, and professed, certainly much to my astonishment, to have room for as many as two hundred patients. It presents no features of any interest as a building; and its wards are small, dirty, and badly ventilated, and crowded with the ordinary class of workhouse inmates, as it is in great part intended to be a benevolent asylum. About ten years ago, when the present house-surgeon, Mr. D. B. Reid, entered it, I was assured by him that it was the favourite abode of pyæmia, erysipelas, and gangrene; and it required no great stretch of the imagination to conceive that it might readily become so again. Mr. Reid showed me an amputation at the shoulder-joint, which was necessitated by the existence of a large fibrous tumour of the humerus, and was complicated by the fact that the head of the bone had been resected some years previously. The flaps were granulating well under carbolic acid and glycerine, on lint covered with oiled silk; and a compound fracture of the leg was also doing well under a similar plan of treatment. The house-surgeon informed me that he had used Lister's plan of treatment since its introduction, and that he had only had one fatal amputation case since, but he could give me no idea of the number of operations he had performed, and there are no statistics kept. Mr. Reid occupies one of those anomalous positions which are common in Australia, though quite unheard of with us. Nominally he is only house-surgeon, with a regularly appointed staff of visiting physicians and surgeons over him; but he is not only at full liberty to do with the patients in the hospital what he pleases, but he is also allowed to practise privately; and, as a very natural result, he is regarded with considerable jealousy by his professional brethren in Geelong, and even elsewhere, as he has managed to acquire (especially among the poorer classes of the community) the reputation of a bold and skilful surgeon. As to the ethical propriety of this accumulation of offices in one person, it cannot be expected that the people of a new colony should retain the same prejudices, or consider this matter in the same light as professional men generally do. One good feature of the colonial character is that great care is taken of the sick poor. In almost every small town, or large village as we would prefer to call them, there is a larger or a smaller hospital, according to the size of the place; and these hospitals have always house-surgeons especially attached to them, sometimes without, but very frequently, as just mentioned, with liberty to practise besides. The remuneration of such an office is seldom very liberal, but it is, in every case, at least infinitely superior to the salary attached to a corresponding position at home.

DISEASES PREVAILING IN VICTORIA. — Apart from phthisis, of which I intend speaking at greater length, the prevailing diseases seem to originate more in the circulatory system than they apparently do at home; and in walking round one of the larger colonial hospitals the number of cases of cardiac disease and aneurism struck me immediately, as being considerably above the average of similar institutions in Europe. That the great prevalence of rheumatism,\* arising from the rapid vicis-

situdes of temperature, may have much to do with the production of this curious fact, is highly probable; but, so long as there is not direct evidence on the subject, it is safer not to trust in a doubtful explanation. Aneurism, and particularly thoracic aneurism, seems one of the most frequent forms of disease in this system, and, so far at least as the Melbourne hospital was concerned, the treatment by large doses of iodide of potassium had not been tried at the date of my visit.

By far the most striking feature, however, presented to the eye of a physician, in going round a colonial hospital, is the constant recurrence, in bed after bed, of cases of hydatids. Hydatids occurring in every organ, seem one of the most common diseases which affect the Victorians; and that they originate in a similar way to that which Hjaltelin has conclusively demonstrated in Iceland, can scarcely be doubted in the land of sheep-runs. The treatment in almost every case is surgical, the hydatid cyst being tapped with the greatest boldness, and without any of the preparatory steps which I have seen employed on the Continent and in Great Britain. I saw the house-surgeon of the Ballarat hospital, Mr. Owen, re-tap three cases in one morning, in whom the previous tapping or tapplings had produced no bad symptoms whatever. It is not customary to inject anything into the cyst; and in the majority of cases I was assured that a single tapping was sufficient to insure the contraction of the cyst, and the recovery of the patient. In one young woman, in the Melbourne hospital, nearly the whole left lung seemed to be the seat of a solid tumour, which was tapped by the house-physician; but the issue of this case I do not know, as I was obliged to leave the colony immediately afterwards. Tapping being thus considered the only necessary remedy, Hjaltelin's treatment by kamela does not seem to have been tried.

Of fevers I have little to say; typhoid, colonial fever as it is called, is not uncommon, and slight epidemics of scarlet fever, too, seem sometimes frequent rather; but typhus can scarcely be said to exist, and small-pox has only once been introduced epidemically, in mistake for varicella. The quarantine rules seem excellent, and are strictly enforced; and it is well that it is so, for Melbourne, with its open sewers, cesspools, and neglected sanitary regulations, would prove an admirable field for the ravages of such an enemy as cholera. The open sewers of Melbourne are often supposed to be merely drains for the surplus rain and the ordinary supply of water from households, but the stench from them indicates that they are much more, and receive urine and stale water with all kinds of impurities in it. The cesspools (of which there are said to be 10,000 within the city limits alone) are known to leak so much that no cellar or basement in dwelling-houses is safe from pollution by them; and although some praiseworthy efforts have been lately made to replace them by closets, with iron buckets for the collection and removal of the solid matters, these attempts at ameliorating the evil seem to have attracted but little attention to what every Melbourne man ought to consider the chief public question of the day. And besides, this lamentable system, or rather want of a system, of sewerage, is greatly aggravated by the large swamps existing between the city and the sea; there being said to be as many as 3,000 acres still nearly constantly under water, while about one-half more of the same swampy ground has been built over. As this land receives a great amount of the drainage from the city, it is obvious that the effluvia generated over such an extensive space would alone suffice to poison the whole population. If we take the absence of epidemics into account, we cannot be surprised to find that the mortality of Melbourne compares unfavourably with that of many of the larger English towns, more particularly with that of London.

It has frequently been asserted—and there certainly exists a very general impression among the public in Melbourne—that the climate of

\* In the year 1869, there were received 252 patients with rheumatism into the Melbourne Hospital, or nearly 1 in every 13 patients admitted.

Victoria, but more especially of Melbourne, is peculiarly fatal to infants and young children; and the attention of the Medical Society has lately been drawn by one of its members, Dr. Singleton, to the statistics bearing on this point. He affirmed that the mortality was even greater than had been very generally supposed, and showed, by the figures which he presented, that for the years 1866, 1867, and 1868, more than 500 out of every 1000 deaths were those of children under five years of age, and that in some of the suburban boroughs of Melbourne the mortality under that age reached the alarming proportion of 70 per cent. Mr. Archer, the Registrar-General of the colony, at a subsequent meeting of the Society, after correcting an error into which Dr. Singleton had fallen about the English mortality at the same ages, merely confirmed the doctor's statements, and supplemented them by showing that in the cool months of the year (June to November) the mortality was only about 33 per cent. of the total deaths, while in the hot months—December to May—it had risen to 66½ per cent. of the whole. Mr. Archer's statement, however, that this mortality, large as it is, does not contrast unfavourably with that of London or of the large English towns generally, must be founded on some serious mistake, to solve which I have gone through the latest returns of the English Registrar-General, Dr. Farr, very carefully. Those returns are for the year 1868—a year in which, Dr. Farr observes, the exceptional character of its meteorological results are most strikingly reflected in the death-rate of children—a comparison of the mortality of males in 1868 with that of the previous year, when no such unusual climatic conditions prevailed, exhibiting an increase at each quinquennium under 15 years of age, while the rate was less than that of the preceding year at the ages 15, 25, and following decennia. Among females, this excess in the mortality of children under 15 was even more remarkable, while in all the successive stages of life above that age the rate of mortality in 1868 was below that of the previous year.

Among males, this excess of mortality was chiefly noticeable, however, in children under five years of age, and this more especially in the unhealthy districts as compared with the healthy. Thus in the former it amounted in this class to a death-rate of 71.36 per 1000 living, while in the latter it was only 43.48 per 1000 living. Among girls under five years of age, the rate per 1000 living, in 1868, was 62.46 in the unhealthy districts, while in the healthy it was only 37.20.

Out of the whole number of male deaths (247,107) occurring in England and Wales in the same year (1868), 108,325, or 43.84 per cent., occurred at ages under five years. At the ages from 5 to 10 the mortality was only 4.10 per cent., while it had fallen to 1.98 at the ages from 10 to 15, so that in reality to every 100 deaths of males at all ages, barely 50 per cent. occurred below 15. Among female children it was even less. Thus of the 233,515 deaths in this class at all ages in 1868, 94,804, or 40.60 per cent., were those of children under five years of age. At the ages from 5 to 10 the mortality was 4.12 per cent., and at 10 to 15 it was 2.06, or a total mortality under 15 years of age of 47 per cent. Of the total male and female deaths occurring in England and Wales in the year, the mortality under five years of age is thus easily seen to be only 42.26 per cent.

In London in the same year the male mortality under five years of age was 46.16 per cent., or 17,427 deaths during this period, out of a total male mortality for the year of 37,753. Among females it was lower; the total number of female deaths for the year being 36,045, of whom 15,353, or 42.59 per cent., were under five years of age, while the combined male and female mortality in those years of life is thus only 44.41 per cent., or considerably lower than that of Melbourne. Indeed, the total male and female mortality under 15 years of age in London is not quite equal to the Melbourne death-rate under five years of age, as the same returns from which I quote show it to be only 49.48 per cent. In my opinion, too, it is scarcely fair to compare the two places without taking into account the gigantic size of London, and its epidemics and constantly prevailing zymotic diseases. The latter class of diseases, indeed, is always very destructive in our large English towns, and more particularly to the children under the ages we have been speaking of; nor was the year 1868 any exception to the general rule of a large zymotic mortality in London. The total number of specified causes of deaths of all classes in the year 1868 in the metropolis were only a very few hundred fewer than the total number of deaths, or 71,481 out of 71,798, as we have already mentioned. Of these, no fewer than 18,641 deaths are registered as from zymotic diseases, or nearly one fourth the whole number. Unfortunately, the number of deaths of children under five years of age from this class of diseases is not given; but it may be taken as granted that the mortality from zymotic causes in Melbourne is fortunately by no means so large. As London, however, has too large a population to compare it fairly with a small city like Melbourne, let us see how the mortality of children in Edinburgh contrasts with that in the capital of Victoria. The

population of Edinburgh has just been returned by the census of this year as 196,500, while that of Melbourne is estimated in 1869 as nearly 180,000; and in the last report of the Registrar-General for Scotland for the year 1870, we find that the mortality of all children under five years of age in Edinburgh only amounts to 33.5 per cent.—a most favourable state of affairs as contrasted with the Melbourne returns; while in reality the average mortality of the entire population is considerably greater in the northern city than in the Queen of the Antipodes, the death-rate for this year being 26.3 per 1000 living in Edinburgh.

The connection between this excessive mortality among the young, and the open drains, cesspools, and swamps, of the southern city, with their poisonous exhalations, is, fortunately for the inhabitants, very evident: fortunately, I say, for, with such facts before them, the remedial measures are obvious.

While dealing with the question of diseases prevailing in Victoria, let me here state that one very important alleged discovery by an Australian physician is still *sub judice*—I allude to Professor Halford's cure of snake-bite by the injection of ammonia into the veins. That it is not an antidote to the snake-poison—as the public erroneously suppose—is a matter of course; but Dr. Halford claims that many cases of recovery which had been treated in this way would inevitably have perished if left to the old methods; while others—as Dr. Scott of Hamilton, and Mr. Webb of Ansherot—report cases of failure in its use. It is impossible as yet to arrive at any just conclusion from the facts which have been brought forward.

[To be continued.]

## SPECIAL CORRESPONDENCE.

### BERLIN.

[FROM A SPECIAL CORRESPONDENT.]

*The Minister of Education and the Scientific Board.—Politics and Professorships.—How Professors are appointed.—New Pathological Laboratories.—Increase of Medical Students at Greifswald.*

IN Germany, the Minister of Education has to attend to a number of other matters besides education. His title, indeed, is that of *Cultus-Minister*, or Minister of Public Worship; and his portfolio includes, in addition, everything relating to public hygiene, education, and the fine arts. There are many people in Berlin who think that to take charge of the State religion on the one hand, and to superintend the amusements, health, and education of the people on the other, are duties requiring administrative talents that cannot well coexist in the same individual; and, as regards the present *Cultus-Minister*, Herr von Mühler, there can be no doubt that he often encounters circumstances in which he sees a divided duty. The most recent act of the unpopular minister has created no small stir in medical circles, and has even furnished one of the comic papers with a subject for its cartoon. The *Cultus-Minister* has certain committees or boards under him, one of which, the Scientific Board, takes action in all matters relating to the public health. The members of this Board are the most distinguished of the medical professors in Berlin; and it was presided over till lately by an eminent member of the medical profession, with the rank of an Under-Secretary of State. On his death a short time ago, the vacancy was filled by the appointment of Professor Frerichs, already a member of the Board, but, in point of priority, not one of the senior members. As soon as the appointment was announced, three of the most active and eminent members, Von Langenbeck, Martin, and Virchow, resigned their seats; and the last named professor wrote to the papers that Dr. Frerichs had not that weight among his colleagues to entitle him to the post, and that the Board must inevitably lose its usefulness under his presidency. Various reasons for Dr. Frerichs' appointment have been suggested, one of which is, that the professor is the family physician of Herr von Mühler. This, however, has been semi-officially denied. It is, however, perfectly well known that Professor Frerichs, like Herr von Mühler himself, is a man of conservative, not to say reactionary, principles in politics; and the real ground of offence in the appointment is probably that it has been dictated by party spirit or other considerations not pertinent to the case. It does not seem probable that the resignations of three of the ablest members of the Board will have any effect on Herr von Mühler, although he has been defeated before now through the same tactics.

It cannot but seem surprising that the appointment of a man so widely and favourably known as Frerichs is should have called forth so outspoken an opposition; and one can only find in this incident another illustration of the maxim that, in appointments such as this, and in the election of university professors, no other consideration but

that of efficiency is to have any weight. Another illustration of the same thing is to be found in the circumstances connected with the election of a successor to Oppolzer at Vienna, where a great clinical professorship has been standing vacant; and, though this delay points to a conflict of interests, it also betokens clearly enough a high sense of responsibility impressed upon those who have the patronage. From the opposition that they have excited, both the Frerichs affair and the appointment at Vienna may be regarded as exceptions of the kind that prove the rule; and they at the same time prove clearly enough that, if in Germany the best man is usually chosen for the post, the cause of this is not, as has been alleged, that the patronage is exercised by a Minister of State. It is hardly an exaggeration to say that the man who is best entitled to this or that vacant professorship in science or in medicine can be pointed to in much the same way as at Cambridge one may hear who is to be the first wrangler on the next occasion. In both cases, the antecedents of the individual—the work that he has done—are freely canvassed; and they constitute the reliable data to judge by. The whole system of study at a German University is calculated to bring the able and zealous workers in any department into the clearest prominence. A student, as he advances in his studies, develops a talent for this or that particular branch, which he is at liberty to follow out unrestricted. He enters a laboratory, and there undergoes a course of training; and, when he has passed his professional examination, if he have a mind, he is encouraged to resume his work in the laboratory; and in course of time he completes some original research, as in physiology or pathology. Then, if he have shown himself a capable worker, he gets the next vacant assistantship; and if, as an assistant, he do not in the course of a year or two make some considerable contributions to the researches in his department, he is looked upon as falling short of his duties, and he will probably lack advancement. If, however, as is usually the case, he avail himself of his many opportunities, and undertakes researches to clear up this or the other doubtful point, he becomes favourably known to the scientific world; and in due time, and while he is yet a young man, he is rewarded with a professorship. And so, within a very few years, the Pathological Institute at Berlin has furnished from its assistants no fewer than five professors to various universities. These are Hoppe Seyler, Von Recklinghausen, Klebs, Kühne, and Cohnheim; and the important work that these men have done testifies to the excellence of the system in which they were trained, and according to which they were promoted. Another series of names, though perhaps not so remarkable, could be furnished from the annals of the Physiological Institute; and, indeed, there is hardly a great laboratory or a great *clinique* in Germany but can point to similar instances. Again, there are the *dozenten* or lecturers, who reach their position through the same steps as the assistants, and who may have been assistants also. From them, too, the professors are chosen, although this is more the case in the non-medical faculties.

Thus it will appear that efficiency in professorial chairs is secured, more than anything else, by the completely organised system in which the rising generation of scientific workers are trained. When an appointment comes to be made, it is usually done very quietly and to the general satisfaction. The other professors of the faculty in which the vacancy has occurred, agree upon some name, which they submit to the education minister. It does not appear that the professors have an actual privilege in this matter, but no doubt their recommendation is invited, and is seldom or never set aside. The assistant or *dozent* who has been thus nominated, "receives a call" to the professorship, and departs to take charge of an institute, or laboratory, or clinic of his own. He has not canvassed heaven and earth for testimonials; the custom is not known in Germany; and when a German *savant* receives a letter from foreign parts, requesting him to certify to what he can about his foreign *confrère*, he is as much puzzled as if the request had been for a lock of his hair; he has not issued a bulky volume of those monotonous documents translated from every language under the sun, and gathered together from the remotest corners of the educated world—the more remote the better. He finds, however, that his qualifications are known without any effort on his part; and those who have nominated him are content to rely on the long and testing apprenticeship which he has served to his special study. In other countries, again, it sometimes happens that natural, or even hereditary, genius is the only thing that can be appealed to.

Although a stranger visiting Germany is in admiration at the number of laboratories and institutes that he sees everywhere, the Germans themselves are in the habit of grumbling that they have not enough; and, just recently, provision has been made, in the budgets adopted by the legislature, for some considerable extensions. Munich is to have a new pathological institute, separate from the hospital, at a cost of about £16,000, and £4,000 is to be spent on extending the physiological

laboratory. Erlangen, also, another Bavarian University, is to have a new pathological institute. The University of Berlin has had the sum of half a million *thalers* (about £75,000) voted to it for similar purposes. A fourth part of this sum is to be expended on a new physiological laboratory; and it is expected that a laboratory for physics will be built adjoining it. The pathological institute, already very complete, will be enlarged, at the cost of about £3,000, the extension being mostly in the department for pathological chemistry, to which a suite of five rooms will be added, providing accommodation for physiological and physical apparatus. It may be useful to mention that there is a description of the pathological institute at Göttingen, accompanied by plans, written by Professor Krause, the director of the institute. In about one half of the German universities there is an institute for pathology separate some little distance from the hospital; and this arrangement is found to be so convenient, that it will no doubt soon be universal.

Whether it can be attributed to a high degree of efficiency in the teaching staff, and to opportunities for study such as have been mentioned, or whether it be owing to other causes, it is a fact that the students in the medical faculty at Greifswald, a small Baltic town of twenty thousand inhabitants, have increased within the last ten years from 140 to no fewer than 340, which is the number of entries for the present winter. The other faculties appear to have remained stationary.

## REPORTS OF SOCIETIES.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 6TH, 1871.

J. BRAXTON HICKS, M.D., F.R.S., President, in the Chair.

*Gynæcometer*.—Dr. AVELING exhibited his gynæcometer, which consists of a number of uterine sounds capable of being combined in various ways so as to form a hysterometer, a vaginometer, or a pelvimeter. By its means the dimensions of tumours and the angle caused by the deviation of the uterus from the vertical line may be accurately ascertained and transferred to paper.

*Abdominal Pregnancy*.—Dr. ALFRED MEADOWS related a case of so-called ventral or abdominal pregnancy. The patient was aged 22, and was admitted under his care into the Hospital for Women. The abdomen was enlarged to at least the size of pregnancy at full term, though she had only arrived at about the sixth and a half month. The foetal heart could be heard. At the end of a week, symptoms of collapse supervened from internal hæmorrhage, and the patient died. The foetus was found free in the abdominal cavity, its only attachment being by the umbilical cord to a kind of placental mass formed at the fimbriated extremity of the Fallopian tube. Dr. Meadows advocated a more frequent resort to gastrotomy in such cases, not so much with a view of saving the child nor of rescuing the patient when collapse had supervened, as to anticipate that collapse, and, in fact, to remove the growth as soon as a true diagnosis could be formed. Possibly in cases such as this one, and perhaps in certain others, it might not be necessary to remove the placental mass, as this might gradually be absorbed by slow physiological atrophy.—Dr. PROTHEROE SMITH had no doubt of the propriety of performing gastrotomy in such cases, but a difficulty suggested itself in the previous diagnosis.—Dr. GRAILY HEWITT believed that the operation of opening the abdomen ought to be performed when hæmorrhage from rupture of an extrauterine pregnancy threatened to be fatal; but the great difficulty was the diagnosis.—Mr. SPENCER WELLS said that the propriety of operating when a woman was dying of bleeding into the peritoneal cavity, was a very different question from that of operating when her life was not in immediate danger, although extrauterine foetation had been ascertained to exist. In the former case, it might be the clear duty of the surgeon to try to save a patient at any risk from inevitable death. In the latter case, he would give full weight to the consideration that a spontaneous termination of extrauterine foetation was not very uncommon.—Dr. GREENHALGH gave brief particulars of seven cases of extrauterine foetation, with three recoveries and four deaths. Of the former, in one the foetal bones were discharged through an abscess in the left groin; in another, a full grown foetus, in an advanced stage of decomposition, was extracted through an incision in the roof of the vagina; and in the third, the liquor amnii was drawn off by a small trocar and cannula. He was of opinion that gastrotomy might, in many cases, give the patient a better chance than permitting the development of the foetus and secundines to progress.—The PRESIDENT said his opinion, based on many cases, was that a number recovered from severe internal hæmorrhage, while a greater number gave no serious anxiety. If, then, these cases were

not so fatal, he should prefer not to interfere till urgent symptoms arose. The opportunity for such an operation as that suggested seldom presented itself. If any one would look over the records of the cases in the Society's *Transactions* he would see the exceeding difficulty which would have attended the removal by gastrotomy: adhesions in all directions, enlargement of the vascular system into sinuses, the hæmorrhage resulting from the rupture of which would be excessively difficult to stop.—Dr. PLAYFAIR thought the difficulty of diagnosis at an early stage almost insuperable. If the patient survived the shock, or in advanced cases of extrauterine foetation from the first abdominal, it seemed to him that there was much less chance of gastrotomy being successful, owing to the extensive adhesions and matting together of surrounding parts. He thought this procedure a much more doubtful practice than in early cases of Fallopian gestation.—The specimen was referred to a Committee for a report.

A *Tumour* exhibited by Mr. SCOTT at the June meeting, which he had removed from a patient who recovered, was reported upon.—Dr. MEADOWS and Mr. SCOTT believed that the growth was ovarian in its origin. Their report stated that it was almost entirely composed of hard dense fibrous tissue, but having in some places a distinctly reticulated appearance. There were visible under the microscope white fibrous tissue, some elongated fibre-cells, and a few rounded granular cells and granules. At one end of the tumour there was found a portion of the ovary which contained the remains of a ruptured ovisac, half filled with blood. The ovary itself could not be separated from the tumour, and it seemed to the reporters possible that the tumour originated in the fibrous stroma of the ovary, and that its growth in one direction did not interfere with that portion of the ovary which still maintained its normal character, and so far as could be judged, performed its ordinary function.—Mr. SPENCER WELLS appended to the report, that there appeared to be a great number of non-striated muscular fibres in the growth, there being a number of broad banded fibres not affected by acetic acid (as the surrounding bundles of fibrous tissue were), and containing long fusiform nuclei. The remains of the ovary seemed to him separable from the tumour, and while not denying the possibility of a tumour largely made up of non-striated muscular fibres originating in the ovary, he thought it must be excessively rare, as he had never seen one; whereas such tumour originating from the uterus were among the most common of morbid growths.

*Malformed Fœtus*.—A report by Drs. AVELING and EDIS, on the malformed foetus exhibited at the last meeting, was read. The sac which protruded from, and communicated with, the abdominal cavity, was as large as a foetal head. It was formed chiefly by an expansion of the sheath of the umbilical cord, but partly also by the abdominal parietes, which were continued up around its base. The sac contained the liver, the spleen, the greater portion of the small intestine, and a small portion of the sigmoid flexure distended with meconium. No trace of a gall bladder could be detected.

*Ovariectomy during Pregnancy*.—Dr. EUGENE GODDARD read the particulars of a successful case of ovariectomy during pregnancy. The patient was twenty-nine years of age, and in 1870 was found to be the subject of an ovarian cyst, but, as there was no urgent symptoms, the consideration of any surgical treatment was deferred. She then became pregnant; and, about the end of the second month of utero-gestation, Mr. Spencer Wells removed the ovarian cyst. Eleven pints and a half of fluid were withdrawn. The clamp was removed, and the bowels acted on the eighth day. Pregnancy went on uninterruptedly, and a living child was born at the full period. Dr. Goddard said that the compound nature of the cyst precluded the idea of tapping, as also did the risk of peritonitis, suppuration of the cyst, and the formation of adhesions. Premature labour was not induced, because the patient was already beginning to suffer constitutional disturbance from the double burden, and it was doubtful whether, by the time a viable child could be born, they would not have assumed such magnitude as to imperil the patient's safety; whereas, if abortion were induced, the child would be lost and the tumour would remain.—Dr. ROSS related a case in which Mr. Wells had operated under more adverse circumstances, as the lady was much broken down in health at the time of the operation. A small ovarian tumour was diagnosed eighteen years ago. The patient was subsequently married, and Dr. Ross had attended her in four labours. In no instance was parturition attended with any serious difficulty. During gestation the tumour appeared to become smaller. The tumour rapidly increased about a year ago, and Mr. Wells removed it successfully, the patient being about two months pregnant.—Mr. SPENCER WELLS said that the existence of the cyst for eighteen years, and the pressure on its walls of hard bone-like masses, had led to the diagnosis of a dermoid tumour. He had performed ovariectomy four times during pregnancy, and all the patients had recovered.—Dr. BANTOCK said that the diagnosis of pregnancy at an early stage, com-

plicated with an ovarian tumour, was not always easy. In considering the performance of the radical operation in these cases, one fact was worth any number of theoretical objections.—Mr. SCOTT referred to a case of ovariectomy which he had recently performed. The patient had passed through two labours at term in safety.

*Fibrous Elongation of the Uterus*.—Dr. BRUNTON detailed a case of fibrous elongation of the uterus, successfully treated by ergot of rye. The patient was unmarried, and aged 47. The uterus was enlarged to the size of a four months' pregnancy.—Dr. TILT had met with two cases in which the womb had become fibrous in its totality. In one case the uterus was about the size of an ostrich's egg.

## ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, DECEMBER 16TH, 1871.

W. T. G. WOODFORD, M.D., in the Chair.

*The Water-Supply*.—A report was brought up from the General Purposes Committee on the subject of the unsatisfactory state of the water-supply, embodying a resolution that the association requested Government to institute an early inquiry into the quality of the metropolitan waters by an independent skilled analyst, in consequence of the anticipated approach of cholera, and of the uneasiness produced by the Registrar-General's reports, especially as all investigations led to the establishment of a connexion between water and cholera. The report was adopted.

*Sanitary Legislation*.—Mr. W. H. MICHAEL, Barrister-at-Law, delivered an address On Future Sanitary Legislation. He asked at the outset, what were the proper limits of legislation in respect of sanitary measures. Property must have some laws respecting sanitary matters. It was abundantly proved that something more than individual supervision was necessary. One of the greatest difficulties in the future was found to arise from neglect in the past. Men had been allowed to do with their property pretty much as they liked, and defaulting owners were frequently men influential in local boards. These men were a great obstacle to all sanitary improvement. It was, moreover, hard, when men had been suffered without let or hindrance to build houses as they liked, to be called upon now to arrange their houses after a prescribed fashion. How far, then, was sanitary legislation to be compulsory? hitherto it had been, practically, permissive; the infliction of a small fine was ineffectual. The public had plainly a right to say to the owner "*Sic utere tuo, ut alienum non lœdas*." Another difficulty where the population was only sparse. Dividing the matter under two heads, (1) the law as it is; (2) as it ought to be, Mr. Michael said that the present state of things was most unsatisfactory. There were Acts within Acts so complicated and so embroiled that the most learned judges had said it was impossible to understand them. Government itself had proved unable to advise local boards. The consequence was that in some places the boards had fallen through, while in others action was paralyzed. Consolidation of sanitary authority had long been urged, and last session an important step had been made. The next thing to be aimed at was the establishment of one local power. Areas would then have to be rearranged, not in accordance with political boundaries, but actual need and physical conditions. As to the sanitary officers, the medical officers were, at present, mostly men in private practice, and dependent on the very men against whom action ought to be taken. Thus, except in times of epidemic, their hands were tied, and their operations limited to the more obvious nuisances. It was necessary, then, that one general statute should be framed, embodying all existing enactments; and a central authority should be established to supervise its execution. While approving of the measure of last session, he considered that sanitary measures ought not to be confined to the houses of the poor; all ought to be included. He was also averse to the connexion with Poor-law relief. In respect of the mapping out of areas it was hard to draw a fast line; divisions ought to be determined by physical condition, drainage necessities, water-shed, and the like. The areas ought to be extensive enough to pay for thoroughly efficient officers. As to the constitution of local boards, and the difference between urban and rural populations, Mr. Michael maintained that a difference in manner, not in matter, was needed. There ought to be only one authority in each district, and that thoroughly representative. He would propose also the establishment of an intermediate authority of a higher character, such as the Metropolitan Board of Works was to the London vestries, to hear appeals on the spot, and step in when local boards failed to do their duty. It was to be regretted that Sir Charles Addeney's Bill contained no provision of this kind. Inspectors sent down from London would not do; their action came too late. An authority on the spot was needed to prevent in time. Nor were Boards of Guardians competent, as had been seen in the past. The sanitary

officers to be appointed should be thoroughly trained medical officers of health. These must not be, as in times past, merely ornamental adjuncts, but moving powers. They must be men of high intellect, and the field of their operations large enough to afford them a high salary, and to liberate them from private practice. Registration of death and of sickness, instead of being in its present unsatisfactory state, ought to be put under their control. Mr. Michael likewise insisted upon the appointment of a Minister of Health to preside over the Central Sanitary Authority; that compulsory power should be given to join districts for drainage purposes; that additional borrowing powers should be granted; that the incidence of rates should be modified in accordance with advantage received; that medical officers of health should have greater powers for preventing overcrowding, and for dealing with contagious diseases; and that private practitioners should be compelled to give all necessary information.—Dr. STALLARD maintained that it would be impossible for any authority to carry out what was against the public opinion of a district. He objected to harsh compulsion; people must be educated. If the Central Authority had the power of granting or withholding a certain share of the expense, that would prove a far more efficient weapon than compulsion.—Mr. HOLLAND advocated inspectors sent down from London, as being free from local jealousies and prejudices, and as having wider experience. He was in favour of the medical officer devoting his whole time to his office.—Dr. HARDWICKE agreed as to the desirability of most of the proposals of Mr. Michael, but doubted whether the sanction of Parliament could ever be obtained for them.—Dr. BARCLAY spoke highly of the competency of the Poor-law Medical Officers to act as deputies under the Health Officer. He disagreed with Dr. Stallard as to compulsion.—The CHAIRMAN said that the mere possession of compulsory power was in most cases sufficient. He was in favour of large areas of operation, and of the registration of deaths and sickness being in the Health Officer's hands.

#### MEDICAL SOCIETY OF LONDON.

MONDAY, NOVEMBER 27TH, 1871.

ANDREW CLARK, M.D., F.R.C.P., President, in the Chair.

*Case of Impalement.*—Mr. ALFRED STEER, of Stourbridge, communicated the following case. On the evening of August 9th, 1870, he was called to an Irishwoman, aged 33, who was said to be dying. It appeared that, having finished her work at the top of a corn-rick, she slid off, instead of going down by the ladder. In doing this, she became impaled on the handle of a hay-fork which had been left resting against the stack. With much difficulty the farmer succeeded in pulling the fork out of her body. The woman fainted and was sick; some brandy was given to her. She was placed in a carriage and brought home. Mr. Steer found her lying on a brick-floor; she had lost much blood, was cold and almost pulseless, but sensible, and complaining of great pain in the region of the heart. Breathing was very hurried and irregular. A little blood was flowing from the vagina. On examination, he found this organ uninjured, but on the left side of the uterus, about two inches or less from the os, his index-finger passed to its root into a large, irregularly cut wound, apparently formed at the junction of the uterus with the left ligament. On withdrawing his finger, there was a great gush of blood. Mr. Steer filled the wound with strips of lint, and could have pushed in any amount of this evidently into the peritoneal cavity. The sixth rib was broken midway between the spine and the sternum, and there was considerable emphysematous crackling. A large plaster and body-bandage were applied, and an ether mixture was given. The woman was too ill to be moved, and lay all night on the floor. She vomited frequently the day after the injury, and there were for some days signs of pleurisy. On August 14th, the last of the plugs was withdrawn. From this date the woman steadily improved. On the 21st, all emphysematous swelling had disappeared, and she had become bright and cheerful. The only medical treatment had been a dose of castor-oil repeated two or three times, and a full dose of calomel and opium on the 12th to allay pain and produce sleep. On December 4th, she seemed perfectly well. She has menstruated twice since the accident, and said she sometimes felt a pain after hard work just where the fork struck her. The pike, beyond doubt, penetrated by the side of the body of the uterus, traversed the abdominal cavity, and, impinging on the diaphragm, pushed with such force against the rib as to break it. Mr. Steer attributed her recovery to the circumstance that the rounded smooth large end of the pike entered her body, and not one of the forks; and that, therefore, the intestines were pushed before it, and thus escaped injury.

*Edema of the Lung after Small-Pox.*—The following case was communicated by Dr. WILTSHIRE. Miss P. had small-pox somewhat

severely in July last, and six months afterwards there was considerable anasarca of the lower extremities. There was also a slight cough. One day the dropsy of the legs suddenly disappeared almost completely; and about twelve hours afterwards, severe dyspnoea, violent cough, and expectoration of enormous quantities of glairy phlegm, came on. The attack was so severe that the patient's life was in great jeopardy. In addition to all the signs of oedema of the lungs, the heart was feeble, and there was a little, but by no means a marked, amount of albumen in the urine, which latter was not scanty. The administration of repeated doses of compound jalap powder, ammonia, ether, and digitalis, sweating in hot blankets, and the administration of brandy gave the patient great relief; and under this treatment she rallied, and made a good recovery.

*Webbed-Fingers.*—Mr. WILLIAM ADAMS showed a boy who was suffering from a webbed condition of several of his fingers. He was being treated by Mr. Tamplin's instrument. The case was in the first stage of the treatment. A hole, with its circumference cicatrised, had been made at the base of the webbed-fingers, and a pencil-case could be passed through it. Simple division, Mr. Adams remarked, gave only a slight improvement; a plastic operation gave a better result. Silver rings to make an opening had been used; but Mr. Tamplin's operation, by which a piece of skin was screwed out by means of two plates of metal, was the best. The compressed tissues soon sloughed out, and the hole was well stuffed with oiled lint. The inflammation and general swelling soon passed off. The operation had been done a month, and the edges of the opening were well cicatrised. The remainder of the web would be treated in the usual way by division with the knife.

*Ophthalmic Cases.*—Mr. BRUDENELL CARTER demonstrated the following interesting ophthalmic cases. 1. Injury of the ciliary nerves and choroid in a boy through a blow on the eye (the lids being closed) with a cricket-bat. 2. Double optic neuritis from the presence of a cerebral tumour, without, at present, any cerebral symptoms. 3. Albuminoid retinitis. 4. Injury of the head and spinal column in a boy, with hæmorrhage into the orbit, and protrusion of the ball of the eye after atrophy of the optic nerve. 5. A case of syphilitic retinitis, nearly well.

MONDAY, DECEMBER 4TH, 1871.

ANDREW CLARK, M.D., F.R.C.P., President, in the Chair.

*Apoplexy after Renal Disease.*—Dr. BROADBENT exhibited morbid specimens from a case of apoplexy following disease of the kidney. One kidney had undergone granular degeneration; the other was not much changed. The heart was hypertrophied, and in the left hemisphere of the brain there was a large irregular cavity; the minute arteries were also hypertrophied. The patient was pregnant, but had menstruated regularly. She was seized with convulsions, coma, rigidity, and paralysis of the left limbs. Hæmorrhage came from the middle cerebral artery, and the cavity was situated external to the motor ganglion and motor tract. Dr. Broadbent thought the rigidity was due to disturbance of the motor ganglion and motor tracts.

*Syphilitic Ulcers cured by Skin-grafting.*—Mr. WALTER COULSON exhibited two patients with syphilitic ulcers cured by skin-grafting. The first patient had suffered severely for three years and a half from syphilis. There had been ulcerations in the face, loss of a portion of the nose, and one extensive ulcer on the leg. He was given, at the Lock Hospital, as much as eighty grains of iodide of potassium three times a day. The ulcers on the face healed, but the leg did not. He was also treated at Birmingham with mercurial baths, but without much success. On his return, the man was treated with bark and nitric acid. On October 3rd, five pieces of skin were taken from the left arm, about the size of a pin's head, and transplanted. On October 26th, five more pieces were grafted. On November 1st, all the five last grafts had taken; and on the 20th, the ulcer had healed with the exception of a small spot. The second man had been suffering for two years and a half from a large syphilitic ulcer of the size of a cheese-plate, and had taken seventy grains of iodide of potassium three times a day. On October 3rd, skin-grafting was done, as in the first case, with great success.—Mr. JABEZ HOGG recommended bromide of potassium in syphilis.—Dr. BROADBENT said that the action of the bromides was quite contrary to that of the iodides.—Mr. DE MÉRIC condemned the use of bromides when the iodide could be given. He had advised a little mercury combined with the iodide. He had also transplanted in some cases, but had failed.

*Disease of Cerebellum.*—Dr. HUGHLINGS JACKSON gave the particulars of a case of tumour with cyst in the right lobe of the cerebellum. The striking point in the case, was the existence of double optic neur-

its without obvious impairment of sight. There were severe headache and urgent vomiting. Very remarkable intermissions in these symptoms occurred, the patient seeming to be quite well in the interval. Later, palsy of both sixth nerves occurred, one before the other, and there seemed trifling difficulty in walking, but there was no limb affection.

## CORRESPONDENCE.

### ON TRIPLE SOUNDS OF THE HEART.

SIR,—In your last number's report of the discussion on Dr. Habershon's case of triple heart-sounds, at the Clinical Society on December 8th, I am erroneously reported as ascribing the aggravation in the case to the fresh complication of aortic disease, whereas I really attributed it to the addition of the mitral lesion. I further associated with this my explanation of the triple sound of the heart, which is altogether suppressed in the report. Now, as this explanation is connected with a proper comprehension of the causes of the sounds of the heart in health and disease, which seem to be still imperfectly understood, I trust that I may be excused for briefly adverting to the subject.

Although many views have been broached and experiments performed since those which I conducted in 1835, yet, so far as I know, the conclusions then arrived at, as to the causes of the heart's sounds, have never been set aside. At that time, and ever since, in all my works and lectures, I have ascribed the first or systolic sound to the tightening of the walls of the heart—valves as well as muscles—by muscular contraction; and the second, or diastolic sound, to the tightening of the arterial valves by the recoil of the arterial column of blood on them.

The first, or systolic sound, although normally one, has not the same quality or duration in all parts of the heart. In the auricular valves, and in the thin walls of the right ventricle, the sound is loud and short, from their more sudden and simple transition from slack to tight. In the walls of the left ventricle, the sound is duller and more prolonged from the more gradual tightening of their thicker mass. The first tightening of the valves gives the flapping commencement of the first sound, which is prolonged by the continued vibration of the thicker muscular walls to the end of the systole: but, although varying in quality and loudness in different parts of the heart, the systolic sound is normally one and continuous.

"Sometimes the systolic sound, without being longer than usual, seems broken into two by something like a flap in the middle; or, to enunciate it, instead of being 'lubb-dup' as usual, the first and second sounds are 'ballub-dup'. I am doubtful as to the cause of this variety, but I think it probable that it may depend on some irregularity in the action of the auricular valves, by which their tightening, with its attending flap, is either delayed or takes place in two successive jerks" (*Lectures in London Medical Gazette*, 1838). Subsequent experience has verified this conjecture, for I have observed several instances in which mitral regurgitant disease was preceded by a double systolic sound, as in Dr. Habershon's case.

This is not the only mode in which the systolic sound may become double, for I have proved that the striking of the apex against the ribs, and possibly even the contraction of the auricles, is capable of producing an apparent reduplication of the first sound (*Pathology and Diagnosis of Diseases of the Chest*, 4th ed., p. 212). The possibility of two ventricles contracting, not simultaneously, but in succession, is much more questionable, when the continuity and close interlacing of their fibres is considered; but, although they act simultaneously, if one act on a normal, and the other on an abnormally loose valve, the sound of one tightening before the other is quite possible and intelligible: and when the loose valve recedes into the auricular orifice, so far as to permit regurgitation, then there is no tightening flap at all, but the prolonged vibration of the reflux murmur. I have met with cases of mitral disease, in which some beats were attended with a murmur and others with the double sound, the regurgitation being only occasional.

It is obviously desirable to distinguish this class of *cantering* or triple heart-sounds from those which arise from reduplication of the *second* sound, which long ago I endeavoured to express phonetically by the words *lubb-dwup*, or *lubb dwup*, and ascribed to successive (instead of simultaneous) tightening of the two sets of arterial valves. It is by no means easy, however, in all cases to make this distinction—to determine whether the reduplication is in the first or second sound. The ventricular impulse, when distinctly felt, is the surest index of the systole: where this fails, the pulse felt in the carotids comes next as a guide. A double sound accompanying these may be pronounced systolic; a double sound distinctly following them may be judged to be

diastolic, and may often be traced also into singularity respectively along the aorta and pulmonary artery.

The diagnosis of valvular murmurs, which I had the good fortune first to describe and to designate by the terms "obstructive" and "regurgitant",\* are also in some degree available to distinguish between ventricular and arterial valvular sounds, as well as murmurs. The mitral and tricuspid share in the natural systolic sound will be heard best where they are best conducted to the walls to which we listen—at or near the apex in the case of the left ventricle; higher up and to the right in case of the tricuspid. The double arterial sound will be heard over the valves at and to the left of the mid-sternum; but the sound of each set will be separate and single on following the course of their respective arteries.

I should expect that the sphygmograph and cardiograph would supply additional information on these lesions.

Dec. 18th, 1871.

I am, etc.,  
C. J. B. WILLIAMS.

### THE MEDICAL DECLARATION RESPECTING ALCOHOL.

SIR,—Will you do me the favour to publish the following remarks, the substance of a letter which I addressed to the President of the Royal College of Physicians in reply to a letter he wrote to me enclosing a printed copy of the medical declaration respecting alcohol?

..... Who of us has a right to charge any members of our profession with "inconsiderately prescribing" for their patients? Surely such a charge, if I rightly interpret the words, infers incapacity, or something worse, in the prescriber—a charge which, I presume, no medical man, however eminent, would thoughtlessly, and still less wilfully, direct against a fellow-practitioner.

The "Declaration" declares that this inconsiderate resort to the employment of "large quantities" of alcoholic liquids or "beverages" has given rise, in "many instances", to the formation of intemperate habits. On whose authority is this statement made? Will it bear the test of critical inquiry? Judging by my own experience, such a result is most exceptional—indeed, I can hardly recall a single well-marked example in which a habit of intemperance has been fairly attributable to treatment of which alcoholic stimulants formed a prominent part. I have rather observed the contrary—viz., that repugnance to alcoholic drinks has followed treatment by such agency, excepting in persons previously addicted to the consumption of spirituous liquors.

Is it quite true that no medical man should prescribe alcoholic stimulants without a sense of grave responsibility? I presume it may be inferred that no practitioner prescribes alcoholic stimulants except on principle, and in the belief that such treatment is more suitable to the case than any other. If so, what becomes of the grave responsibility? In the passage, that every medical practitioner should endeavour to inculcate habits of moderation in the use of alcoholic liquids, I quite concur, though I do not see very clearly the mode or the opportunity that may be afforded him of giving other than general advice on the subject of such simple and unstimulating diet as I presume every medical man would recommend for adoption. But all this refers to health and not to disease. There can be no doubt that treatment by stimulants is adopted more liberally by some practitioners than by others; but this is the result of experience, based, we may presume, on principle. Can you induce those persons who are termed in the "Declaration" "inconsiderate", to change their principle and forget their experience? I am as fully alive to the evils of intoxicating drinks as any man, and I have not been unobservant of their influence whether in the persons of invalids, of general society, or of the working class.

With respect to the alleged excesses charged against and constituting a habit of society, I believe they are greatly exaggerated, though I acknowledge that the consumption of wine by young persons under social excitement occasionally exceeds the boundary of moderation.

With regard to the influence of alcoholic drinks and of intoxicating liquors on the working class of society, my sentiments are expressed in a letter which I wrote to Dr. Burrows last August, which an attack of illness prevented my sending him, and in which I addressed the President to the following effect.

"There is, as we all know, a great contest in progress between the sellers of intoxicating liquors and the law-makers of this country. It is acknowledged that the authority of the Government is scarcely sufficient to amend the law with a view to check the very injurious supply of intoxicating drinks, now consumed by the people, so fatal to their

\* *Pathology and Diagnosis of Diseases of the Chest*. Third Edition. 1835. In March 1836, I published in the *Medical Gazette*, illustrating the successful application of these rules of diagnosis, verified by *post mortem* examination. Dr. Hope proposed similar rules, but not till three years later.

moral and physical health throughout the land. I conceive there to be no class of society so competent as the members of our profession to give testimony to the injurious influence on the constitution from habits of intemperance; and that the expression of this conviction on their minds, emanating from the governing bodies of the Colleges of Physicians and Surgeons, could not but exercise a powerful influence on the mind of the Government."

The remainder of the letter merely referred to the best means I could suggest for carrying this object into effect, and requesting that Dr. Burrows would give the subject his earliest consideration.

I object to the "Declaration". 1. Because it is dictatorial, assailing the deliberate judgment of a large number of honourable and intelligent members of our profession; 2. Because the facts on which it is based are very questionable; 3. Because I believe the first two paragraphs will prove inoperative to any useful purpose.

I am, etc.,

F. C. SKEY.

24, Mount Street, Grosvenor Square, Dec. 26th, 1871.

## OBITUARY.

### PATRICK MILLER, M.D.

DR. PATRICK MILLER, Senior Fellow of the Royal Society of Edinburgh, Fellow of the Royal Medical and Chirurgical Society, and Consulting Physician to the Devon and Exeter Hospital, died at his residence, The Grove, near Exeter, on December 24th, aged 89. He was born on May 21st, 1782, and was the eldest son of the Rev. Thos. Miller, minister of Cumnock, Ayrshire, and of Janet, daughter of Dr. Matthew Stewart, D.D., the celebrated Geometrician and Professor of Mathematics in the University of Edinburgh. He was educated at the High School, Edinburgh, under the accomplished Alexander Adam, and subsequently at the University of Edinburgh, under the eye, and for a large portion of the time beneath the roof, of his celebrated maternal uncle, Dugald Stewart, Professor of Moral Philosophy, and author of the *Elements of Moral Philosophy*. The beautiful marble bust of Dugald Stewart which is now in the library of the University was a recent present from his nephew now deceased. While he was thus pursuing his general and medical studies, his social advantages were very great, and he formed friendships with many who, in subsequent years, became eminent for their talents and usefulness. Amongst others, were the late Lord Palmerston, Lord Lansdowne, and Lord Brougham. His friendly intercourse with these only ceased with their deaths. The medical and scientific schools of Edinburgh were at this period brilliantly upheld by men of surpassing talent, including Cullen, Duncan, Monro *secundus*, Home, and Joseph Black, the celebrated physician and chemist. From these Dr. Miller received the impulse which directed his studies to the accomplishment of a vast field of information and usefulness.

In 1804, Dr. Miller graduated as M.D., and three years afterwards (1807) took up his residence in Exeter. In 1809, on the resignation of Dr. Dyer, he was elected one of the physicians of the Devon and Exeter Hospital, an office which he retained for fifty years, only resigning it in 1860. In connection with this a somewhat remarkable fact may be mentioned, that the person who proposed his election on the former occasion, moved the vote of thanks which was passed to him on the latter; and this was the late Sir Thomas Dyke Acland, who died only three months before him. In 1818, on the foundation of the Exeter Dispensary, Dr. Miller became one of the physicians. In 1822, Dr. Daniell resigning, he was elected Physician to the Lunatic Asylum at St. Thomas, near Exeter. This office he retained for forty years, resigning it in 1861. He early gained the esteem of the public, and became, with the late Dr. Blackall, a leading physician of the county.

He had a large and capacious mind, and brought to bear upon the practice of his profession the resources of that mental culture which had distinguished his early career. He was the safe and judicious practitioner; the friend that advised with kindness, and solaced the sufferings of disease; always courteous in consultation. His softness and kindness of manner were nevertheless characterised by great and unusual energy, and he by no means limited his time and activity exclusively to his professional duties. A robust frame and great bodily health and strength enabled him to accomplish more than most men could have ventured to engage in. He took his share in the service of the public as a magistrate, as a trustee of the Exeter charities (his name being on both the church and general lists), and as a member of the committees of the various charitable institutions of the city. He was one of the original promoters of the Devon and Exeter Institution, the Central School, the Savings' Bank, the Penitentiary, the Institution for the Deaf and Dumb, the Infant School, the Institution for the Blind,

the Dispensary, the Water Company, the Refuge, etc. On the development of the railway system, and when people for the most part looked coldly and opposingly on the schemes proposed, Dr. Miller gave them his cordial approval and support, and assisted as director in the projecting, construction, and management of the Bristol and Exeter railway, and subsequently of the South Devon and Cornwall railways. Until the last eight years, when bodily suffering, from rheumatism, interfered with his activity, he continued in the unceasing discharge of his various duties, and he brought to them not only a matured judgment, but a refined mind. He was courteous in all his transactions with his fellow men, and his conduct was characterised by the sincerest friendships for those whom he esteemed; while at the same time he displayed a marked reticence concerning the faults and failings of those of whose conduct he could not approve. It was rare, indeed, to hear Dr. Miller utter a word or a sentiment which could in any way be grating to the feelings of another. When locomotion became difficult to him from the increase of his rheumatic pains, he took interest in books and the current literature; he read the livelong day. The vigour of his mind was complete to the very last moments of his existence, and he retained the most accurate and particular memory of things gone by, while taking the minutest interest in all the notable events of the passing time. The past summer witnessed him wheeled in his chair round his garden, noticing with interest the trees, fruits, and flowers which he had himself planted, and often calling attention to roses, many of which had been budded by his own hand. Amid all his anxious duties, his garden had been to him a solace and a delight.

In 1818, he married Ann Julia, third daughter of General the Right Hon. Sir George Hewett, Bart., G.C.B. She died in 1833, having had ten children, of whom four only now survive; viz., two sons, Colonel Dugald S. Miller, formerly of the 67th Regiment, and Captain Henry M. Miller, R.N., and two daughters. He married secondly, in 1842, Elizabeth, daughter of the late Rev. William Barker, Rector of Silverton. She died in 1851 without surviving issue.

### JOHN NALTY, M.D., DUBLIN.

DR. JOHN NALTY died on Dec. 6th, aged 73, in Dublin. His practice was considerable, especially amongst families of respectability, who reposed a trust which was well founded in his knowledge and experience. He received originally a fair classical education, and completed his apprenticeship to the late State Apothecary, Mr. Hunt. Upon the death of that gentleman, Dr. Nalty was elected resident apothecary to Sir Patrick Dun's Hospital, a situation which he held for some years. He afterwards proceeded to Edinburgh, where he obtained his degree in 1834. He subsequently went to London, and became a member of the Royal College of Surgeons. Returning to Dublin, he followed his profession as a general practitioner for forty years with credit and success. For many years he took, as Vice-President, an active part in the administration of the Poor-law in the South Dublin Union. Here his medical knowledge, his rare punctuality, and assiduous attention to whatever he undertook to do, with his thoroughly impartial mind, enabled him to render essential service to the public, and, in a country distracted by parties, to be respected by all.

### MATTHEW JACKSON, ESQ., MARKET WEIGHTON.

WE regret to record the death of Mr. Matthew Jackson, of Market Weighton, which occurred on November 30th, from an attack of apoplexy lasting but a few hours. He was a man universally respected, following his profession quietly and without ostentation. Few men, perhaps, in his sphere possessed more eminently the esteem and confidence of his patients, and his death will long be felt by those who knew his many and varied qualifications. He was an old member of the British Medical Association, of the Medical Benevolent Society, etc., and had been in practice at Market Weighton for above forty years.

### WILLIAM T. GILDER, ESQ., MARGATE.

MR. GILDER, who died in the eighty-fourth year of his age on December 10th, was born at Margate in 1788. For several years he served as Assistant-Surgeon in the Scots Fusilier Guards, being with his regiment at Walcheren and the Peninsula. He received from the Horse Guards a war-medal with three clasps, having been present at Nive, Nivelles, and Vittoria. On leaving the army, he settled in Queen Anne Street, London, and practised successfully for nearly forty years. On retiring from practice in 1850, he took up his residence in Margate, where he died. He was a justice of the peace for the Cinque Ports.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 21st, 1871.

Beardsley, Arthur Arnold, Grange, Lancashire  
Chilcot, James, Southsea  
Cowley, John Selwyn, Upton-on-Severn  
Griffiths, William Edwin, Kensington  
Langley, Frank, Lewes, Sussex  
Parkes, William Edmund, Handsworth  
Richards, John Edward, Ruabon, North Wales  
Sayer, Charles Wathen, Sutton, Somerset  
Searle, George Clement, Tewkesbury  
Sergeant, Edward, Leeds  
Sharpe, George Metcalfe, Hunslet, Leeds  
Wallis, Edward Darley, Bodmin, Cornwall  
Wilkinson, Joseph Craddock, Spalding  
Willis, George, Soham, Cambridge

The following gentlemen also on the same day passed their first professional examination.

Atkins, Francis Thomas, Guy's Hospital  
Barrow, Frederick, King's College  
Bromley, John Maddan, University College  
Bryan, Clement Frederick, Guy's Hospital  
Crouch, Ernest John, Charing Cross Hospital  
Keer, George Edwardes, Guy's Hospital  
Nash, William Gunner, Guy's Hospital  
O'Brien, James Octavius, Guy's Hospital  
Page, Herbert Markant, Birmingham Hospital  
Saer, David Protheroe, St. Mary's Hospital  
Tayler, Herbert Price, Guy's Hospital

**As Assistants in compounding and dispensing medicines.**

Anthony, David, Cardiff  
Bannerman, Charles Alexander, Preston  
Hensley, Robert Place, Mildenhall  
Perks, Samuel Woodhouse, Hitchin

**UNIVERSITY OF DUBLIN.**—Winter Comitia, December 20th, 1871.

**Bachelors in Medicine.**

Blunden, Maurice R.  
Bryant, Thomas John  
Cannyn, Henry  
Ellis, Thomas  
Irvin, Fitzjohn Robert

**Masters in Surgery.**

Blunden, Maurice R.  
Cannyn, Henry

**Doctors in Medicine.**

Bryant, Robert  
Duff, George Frederick

M'Allister, Alexander  
MacMullen, Hamilton  
Nesbitt, Dawson  
Scott, Harvie  
White, Richard Dormer

O'Connor, James  
White, R. D.

Skelton, James Marshall  
Steele, William Henry

## MEDICAL VACANCIES.

The following vacancies are announced:—

**AXBRIDGE UNION, Somersetshire.**—Medical Officer and Public Vaccinator for District No. 11: £400 per annum, and extra fees.  
**BELFORD UNION, Northumberland.**—Medical Officer for the Eastern District: £200 per annum.  
**BRIGHTON AND HOVE DISPENSARY**—Two Surgeons.  
**CARMICHAEL SCHOOL OF ANATOMY, MEDICINE, and SURGERY,** Dublin.—Lecturer on Anatomy.  
**CARNARVONSHIRE and ANGLESEY INFIRMARY and DISPENSARY,** Bangor.—House Surgeon: £20 per annum, board and lodging.  
**CHONTALS CONSOLIDATED MINING COMPANY, Nicaragua.**—Resident Surgeon: £200 per annum, passage and house free.  
**COOTEHILL UNION, co. Cavan.**—Medical Officer for the Drum Dispensary District: £200 per annum, and fees.  
**EAST LONDON HOSPITAL FOR CHILDREN and DISPENSARY FOR WOMEN.** Surgeon.  
**EAST SUSSEX, HASTINGS, and ST. LEONARD'S INFIRMARY.**—Physician.  
**FEVER HOSPITAL and HOUSE OF RECOVERY, Dublin.**—Temporary Physician; Temporary Surgeon.  
**GOREY UNION, co. Wick.**—Medical Officer and Public Vaccinator for the Kilkenny and Wexford Dispensary District: £200 per annum, and fees.  
**HOLLOWAY and NORTH ISLINGTON DISPENSARY.**—Assistant to the Resident Medical Officers: £200 per annum, to commence.  
**JERSEY GENERAL DISPENSARY.**—Resident Visiting and Dispensing Medical Officer: £200 per annum, furnished rooms, attendance, coal, and gas.  
**KILBURN UNION, co. Clare.**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Clonsilla Dispensary District: £100 per annum, and fees.  
**LANCASHIRE LUNATIC ASYLUM, Preston.**—Medical Superintendent: £200 per annum, house (partially furnished, and free of rates and taxes), coal, gas, and washing.  
**LEMURE UNION, co. Waterford.**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Lemure Dispensary District: £200 per annum, and fees.  
**LIFFLYN UNION, Montgomeryshire.**—Medical Officer for the Llanfihangel District: £200 per annum.  
**LONDON DRY UNION.**—Medical Officer for the Kiln Dispensary District.  
**LOYAL UNITED BRETHREN BENEFIT SOCIETY.**—Surgeon.

**MEATH HOSPITAL and COUNTY OF DUBLIN INFIRMARY.**—Surgeon-tendant of the Female Department: £600 per annum, furnished house, rates and taxes free, coal and gas.

**MIDDLESEX HOSPITAL.**—Resident Physicians' Assistant; Resident Obstetrical Assistant.

**NEWARK HOSPITAL and DISPENSARY.**—Resident Medical Officer and Secretary: £100 per annum, board and lodging.

**NORTH WALES COUNTIES LUNATIC ASYLUM, Denbigh.**—Assistant Medical Officer: £80 per annum to commence, rooms, board, and washing.

**POCKLINGTON UNION, Yorkshire.**—Medical Officer for the Pocklington No. 1 District and the Workhouse: £40 per annum, and extra fees. Medical Officer for the Market Weighton No. 2 District: £19 per annum, and extra fees.

**POOLE UNION, Dorset.**—Medical Officer for District No. 3: £75 per annum.

**ROCHDALE INFIRMARY and DISPENSARY.**—Resident Medical Officer: £80 per annum, board and lodging.

**ROYAL CORNWALL INFIRMARY, Truro.**—House-Surgeon, Secretary, and Dispenser: £120 per annum (rising £10 per annum for three years), furnished apartments, firing, gas, and attendance.

**STOCKWELL FEVER HOSPITAL.**—Resident Medical Superintendent: £400 per annum, unfurnished residence, coal, and gas.

**SUDBURY UNION, Suffolk.**—Medical Officer and Public Vaccinator for the First District: £55 per annum, and extra fees.

**SUNDERLAND INFIRMARY.**—Junior House-Surgeon: £60 per annum, board, lodging, and washing.

**THINGOE UNION, Suffolk.**—Medical Officer and Public Vaccinator for District No. 8: £13 per annum, and extra fees.

**THOMASTOWN UNION, co. Kilkenny.**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Knocktopher Dispensary District: £95 per annum, and fees.

**TUAM UNION, co. Galway.**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Headford Dispensary District: £120 per annum, and fees.

**WEST HAM UNION, Essex.**—Medical Officer for the West Ham No. 2 District: £80 per annum.

**WHITECHAPEL, District of.**—Certifying Factory Surgeon.

**WHITECHAPEL UNION.**—Medical Officer for District No. 4.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

**ALEXANDER, Reginald G., M.D.,** appointed Honorary Visiting Physician to the Bradford New Fever Hospital.

**ALLEN, John Burgess, L.K.Q.C.P.Irel.,** appointed Medical Officer to the Workhouse, Infirmary, and Fever Hospital of the Gorey Union, co. Wexford.

**LEWIS, Lewis, Esq.,** appointed Resident Medical Officer to the St. Pancras and Northern Dispensary.

**NICOL, Patrick, M.D.,** appointed Honorary Visiting Physician to the Bradford New Fever Hospital.

**ROCHE, E. B., Esq.,** appointed Surgical Registrar to King's College Hospital.

**THOM, Alexander, F.R.C.S. Edin.,** appointed Parochial Medical Officer for Madbury, Perthshire.

**WALKER, T. Shadford, Esq.,** appointed Lecturer on Ophthalmic Medicine and Surgery at the Liverpool Royal Infirmary School of Medicine.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

## BIRTH.

**VERNON.**—On December 26th, at Wimpole Street, the wife of \*Bowater John Vernon, Esq., prematurely, of a son.

## DEATHS.

**HUNTER.**—On December 19th, at Wilton Place, Belgrave Square, John Charles Hunter, L.R.C.P. Lond., aged 72.

\***MILLER, Patrick, M.D.,** Consulting Physician to the Devon and Exeter Hospital, at Mount Radford, Exeter, aged 80, on December 24th.

**RICHARDSON, Edward, M.D.,** at Hastings, aged 47, on December 16th.

**VERNON.**—On December 26th, at Wimpole Street, aged 23, Emmeline Agnes, wife of \*Bowater John Vernon, Esq.

**CARBOLIC ACID PAPER.**—A carbolic acid paper, which is now much used in America for packing fresh meats, for the purpose of preserving them against spoiling, is made by melting five parts of stearine at a gentle heat, and then stirring in thoroughly two parts of carbolic acid; after which, five parts of melted paraffine are to be added. The whole should be well stirred together, until it cools; after which, it is again melted, and applied with a brush to the paper, in quires, in the same way as in preparing the waxed paper used for wrapping various articles.

**BEQUESTS, DONATIONS, ETC.**—Mrs. Swan Hood Robinson, of Montagu Square, has bequeathed, in pursuance of her late husband's request, £3500 to the Pension Fund of the National Hospital for Paralysis; £3000 to the Royal Free Hospital; £2000 to St. Mary's Hospital; £500 to the Middlesex Hospital; and £300 to the Western General Dispensary.—"R. T. W." has given a third £1000 to the Hospital for Women.—"H. G." has given a third £1000 to the East London Hospital for Children and Dispensary for Women, Ratcliffe Cross.—Mr. J. Hominan, of Coombe Cliffe House, has given £1000 to the Building Fund of the proposed new Croydon Hospital.—The Worcester General Infirmary has received £145:8:1 under the will of Mrs. Frances Penn.—The Mercers' Company has given Fifty Guineas to the Royal Free Hospital.—The Sheffield Church Burgesses have granted £140 from their surplus funds to the General Infirmary.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY** ..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** ..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** ..... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**TUESDAY**.—Pathological Society of London, 8 P.M. Annual Meeting. Election of Officers, etc. Specimens to be exhibited:—Mr. Sibley (for Mr. Bakewell): Photograph from a Case of Leprosy. Dr. Dickinson (for Mr. Bradley of Manchester): Deformity of Pharynx. Mr. Hulke (for Mr. Hickman): Pea in Lachrymal Canal. Mr. Galton: Perforations of Bowel in Typhoid. Mr. Arthur Norton: Malignant Growth of Femur. Dr. Kelly: Ulcer of Bronchus opening into Pulmonary Artery. Dr. Clifford Allbutt: Sections of Medulla in Hydrophobia. Dr. Clifford Allbutt: Syphilitic Disease in Encephalic Arteries. Dr. Leared: Renal Calculi of Cystic Oxide. Mr. Lawson: Sequel of a Case of Blood Cyst.

**WEDNESDAY**.—Royal Microscopical Society, 8 P.M. Dr. Carruthers, "Fossils of the Coal Measures"; Mr. James Bell, "Fermentation and its results."—Obstetrical Society of London, 8 P.M. Annual Meeting. Dr. Playfair, "On the Treatment of Ectopyema in Children"; Mr. Jalland, "On a Case of Vaginal Thrombus"; President's Address.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week:

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

FOR replies to questions concerning Poor-law medical questions, see Poor-law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Maunsell, Dublin.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

M.B., M.A., is thanked for the correction.

DR. HAWKSLEY is thanked for his courteous communication. For other reasons, we do not propose to use the information.

WE would again request correspondents not to enclose stamps for the return of MSS., and refer them to the standing notice on this subject at the head of this column.

WE have handed Dr. Dale's communication to the publisher, to whom, obviously, both communications should have been addressed.

DR. GRAY (Castellwellan).—It would be useless to publish the letter; for it illustrates not the deficiencies of the Medical Act, great as they are, but the operation of certain rules of evidence common to the English law in general.

H. M. (St. Bartholomew's).—On the 13th and 10th proximo; see our advertising columns, and the numbers of the BRITISH MEDICAL JOURNAL following the respective examinations, where you will find the questions published.

## THE MEDICAL DIRECTORY AND FOREIGN TITLES.

WE have been requested to publish the following letter.

"To the Editors of the Medical Directory.

"30, Gower Street, Bedford Square, December 28th, 1871.

"Gentlemen,—You publicly announced in September last that no foreign qualification would be inserted in the edition of the Medical Directory for 1872. Allow me to express my surprise on finding that in my case the annotation 'M.D. Paris,' is omitted, as also in the case of Dr. Chepmell, while it is not omitted in several other instances.

"If the Directory purports to show the scientific standing of the members of the profession, it must have one and the same rule for all.

"I am, gentlemen, yours truly,

THOMAS COOKE, M.D. Paris, F.R.C.S.E.,

"Ass't Surgeon to and Demonstrator of Anatomy at Westminster Hospital."

MR. LARDNER GREEN'S communication was duly received, and shall have attention.

MR. FURNEAUX JORDAN'S request shall be complied with, if possible. We fear that some of the numbers in question are out of print, and we have no means of procuring them for him.

## THERMOMETER CHARTS.

SIR,—Can you inform me where I can obtain thermometer charts marked with the same number of degrees as are marked on the thermometers? Those published by Messrs. Harvey and Reynolds, of Brigsteed, Leeds, commence with 96 deg. Two cases have come under my observation, where the temperature was frequently as low as 93 deg. Again, it would be better if a wider space were allowed for the registration of the pulse, as it is necessary, in cases of aneurism of the arteries of the neck and upper extremities, to register both the right and the left pulse.

Dec. 18, 1871.

I am, etc., GEO. CHAS. COLES.

ENGLISH POOR LAW.—A Poor-law Medical Officer writes to say that, about a week since, I applied to the Board of Guardians for extra remuneration, on account of the number of small-pox cases I have had under my care at the Dartford Union Workhouse, stating that medical officers of other unions had been rewarded in a similar way. At the weekly meeting of the Board this morning, they requested me to prepare a statement by next Saturday, citing some of the names and the circumstances under which this extra remuneration had been granted. I shall esteem it a great favour if you can furnish me with any names of the recipients, with or without the particulars under which the remuneration was granted.

\* \* The Guardians of the Westminster Union have granted a gratuity to the medical officer of the Petty France Workhouse, for his extra labour during the small-pox epidemic. The Paddington Guardians also awarded a gratuity to their workhouse medical officer; and the Mile-end Old Town guardians have granted a gratuity to their district medical officer; and there are, doubtless, many others that have received gratuities for their services.

## TORSOCCLUSION.

SIR,—Dr. McRae will find particulars regarding the first use of torsocclusion in Sir J. Y. Simpson's work on *Acupuncture*. Let me repeat what I stated in my former letter concerning the properties of the different varieties of iron-wire—viz., hard tempered wire is elastic, annealed wire is inelastic. Mr. Harper, of Aberdeen, one of the most extensive wire-workers in the North of Scotland, has assured me of the correctness of my statement, and has expressed his willingness to give Dr. McRae ocular proof, should he desire it. I am, etc., J. C. OGILVIE WILL.

## VENTILATION OF DRAINS.

SIR,—How would you ventilate drains from a country house? My notion has been to ventilate the cesspool by a pipe projecting about ten feet above the ground, and by this means try to prevent the accumulation of gases, which might, by backward pressure, force the traps and enter the house. I am, etc., A. P.

## PROSTATIC GLEET.

SIR,—A young man, aged 30, has for two years past been troubled with prostatic gleet, for which the many remedies tried have proved unavailing. The prostate is slightly tender and swollen; there is some feeling of tenesmus; in the morning, after micturition, there is a discharge of clear sticky mucus; seminal emissions in dreams are attended with some degree of obscure perineal pain. Blisters to the perineum have been tried with some relief, but not with perfect curative results. These, with cold water enemata into the rectum, as recommended by Sir H. Thompson, are the only plans of treatment that have been found of avail. Can you, or any of your surgical readers, mention any drugs (iron and turpentine have both been tried) or application likely to prove successful in removing the condition? Or you they would thereby much oblige, Yours, etc., A. B. M. A.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Inverness Courier, Dec. 21st; The Bristol Daily Post, Dec. 22nd; The Liverpool Weekly Albion, Dec. 23rd; The North British Daily Mail, Dec. 20th; The Melbourne Argus, Nov. 6th; The Hastings and St. Leonards News, Dec. 22nd; The Ipswich Journal, Dec. 23rd; The Barnstable Times, Dec. 26th; The Lincoln, Rutland, and Stamford Mercury, Dec. 22nd; The Lincoln Journal, Dec. 26th; etc.

## COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. T. Longmore, Woolston; Mr. Furneaux Jordan, Birmingham; Dr. George Johnson, London; Dr. E. Bucknill, Rawtenstall; Mr. T. D. Saunders, Smarden; Dr. Rowan, Kilkee; Mr. Michell Clarke, Clifton; Mr. Brocklehurst, Manchester; Dr. Denton, Bridlington; Mr. Stewart Clark, Allahabad; Dr. John Harley, London; Mr. W. B. Hay, Hull; Le Directeur de la Revue Scientifique, Paris; Zymosis; Mr. R. N. Willis, Rathmines; Dr. F. Harris, London; Mr. J. J. Bunch, Wolverhampton; Dr. Bishop, Paris; Mr. E. N. Smith, Crawley; An Associate; Mr. J. Robinson, Denbigh; Mr. J. Sleman, Gunnislake; Mr. D. P. Evans, Belper; Mr. C. B. Breary, Scarborough; Dr. Miller, Dundee; Mr. E. P. ## PRIZE MEDAL OF THE BRITISH MEDICAL ASSOCIATION

THE HASTINGS GOLD MEDAL, value Twenty Guineas, is offered annually by the BRITISH MEDICAL ASSOCIATION as a Prize for an Essay on some subject connected with Medical Science. The subject selected for competition for 1873 is—"ON THE PATHOLOGY AND TREATMENT OF OVARIAN DISEASES," and the award will be made at the Annual Meeting of the Association in that year. Essays must not be in the handwriting of the Author. Each Essay, which must not exceed in length twenty-four pages of the BRITISH MEDICAL JOURNAL, must be sent, under cover, with a sealed envelope bearing the motto of the essay and containing the name and address of the Author, to the General Secretary of the Association, 37, Great Queen Street, on or before the 1st of May, 1873. The successful Essay will be the property of the Association, and will be published in the BRITISH MEDICAL JOURNAL.  
13, Newhall Street, Birmingham.  
T. WATKIN WILLIAMS, F.R.C.S., General Secretary *pro tem*.

All the New Books and New Editions, in unlimited supply, on the day of publication. Subscription commences at any date. Prospectus on application to H. K. LEWIS, 136, Gower Street, W.C.

### Van Houten's Cocoa.

The only guaranteed Pure Soluble Cocoa, better and cheaper than any other Cocoa, Cocoa Extract, or any Chocolate.

The *British Medical Journal*, March 27th, 1869, says:—"Van Houten's Extract is admirable. In flavour it is perfect, and it is pure, well prepared, and rich and healthy." *The Lancet*, etc., etc.  
"It is a most useful and valuable article of food, and is well adapted for a family, free of charge, through your General or Chemist."  
H. K. LEWIS, 136, GOWER STREET, LONDON, W.C.
